British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EPITOME

OF

Current Medical Literature.

JULY TO DECEMBER 1922.

London :

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
429, STRAND, W.C.

INDEX TO THE EPITOME FOR VOLUME II, 1922.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocoele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

-A.

Abdominal disease, acute, shouider pain in, 484
Abdominal membranes, anomalous, 173
Abdominal pain, diagnostic value of, 12
Abdominal pain, "thermo-penetration" for, 488
Abdominal wall, post-operative hernia of, 363
Abortion, treatment of, 492
Abscess of tongue, primary cold, 37
Accessory sinuses. See Sinuses
Acetonuria, post-operative, 212
Acid secreted by the kidneys, mechanism of neutralization of, 88
Actinomycosis, buccal, 343
Actinomycosis, treatment of, 232
ACTON, H. W.: Causation of iathyrisms, 251
Addison's disease and pregnancy, 240
Adeno-carcinoma of the fundus uteri, 344
Adenomyoma of the uterus, diffuse, 128
Adrenaline reaction in cases of high blood pressure, 68
Adrenaline, resuscitation by the intracardiac injection of, 358
Agglutination, group, 408
AIREVOZ : Lumbago and sciatica, 97
Air passages, upper, surgical diathormy for inoperable growth of, 342
Albee's operation for Pott's disease, 402
Albuminuria and bismuth poisoning, 315
Albuminuria and eclampsia, influence of diet on the incidence of, 83
Albuminuria, orthostatic in pregnancy, disappearance of, 155
Alcoholic epilepsy, 167
ALVAREZ, W. C.: Improvements in pre operative and post-operative care, 422
Amaurosis in infants, some causes of, 208
AMARD : Mechanism of neutralization of acid secreted by the kidney, 88
AMES : Length of life of transfused erythrocytes, 66
ANDERSEN, P.: The blood picture of radiologists, 331
Anaemia, blood transfusion and the treatment of, 170
Anaemia, infantile splenic, 3
Anaemia, pernicious, due to stricture of the intestine, 504
Anaemia, severe, and leukaemia in childhood, 25
Anaesthesia, intraspinal, the causes of fatalities from, 256
Anaesthesia, spinal, followed by meningitis, 511
Anaesthesia, spinal, non-success in, 214
Anaphylaxis in man, fatal case of, 179
ANDREWS, F. W.: Group agglutination, 408
Aneurysm of the uterine vessels, 449
Angina abdominalis, 435
Angina pectoris, 270
Anilin copying ink as a toxic foreign body, 420
Ankylosis of joints, arthroplasty for, 148
ANSCHÜTZ : Palliative trephining for pressure on the brain, 461
Anti-diphtheric vaccination, the effect of, 220
Antidiphtheric serum, action of on lysis due to the bacteriophage of d'Herelle, 410
Antilyphoid vaccination, effect of on the enteric fevers, 520
Antilyphoid vaccination in the German army during the war, 312
Appendicitis the cause of general chronic debility, 126
Appendicitis, sex incidence of, 100
Appendix, radiography of, 441
ARACHNOID fluid, the precipitation test of, 198
ARMAND-DELLILE : Researches on the value of antibodies in tuberculosis, 181
ARNSTRONG: Embryology and physiology of stasis of the colon, 54
Arterial hypertension, 332
Arterio-sclerosis in children, 476
Arthritis chronic, dietetic treatment of, and its relationship to the sugar tolerance, 297
Arthritis, gonocoeal, 340
Arthritis, haemophilic, 93
Arthroplasty for ankylosis of joints, 148
Artificial pneumothorax. See Pneumothorax
Ascariides and urticaria, 53
Ascaris, the mode of infection by, 6
Ascites complicating myoma uteri, 19
Ascites in the female, physiological, 129
Aspirin in asthma, 185
Aspirin as a urinary disinfectant, 165
Asthma, aspirin in, 186
ASTHMA, bronchial, relation between pulmonary and systemic circulation in, 337
ASTHMA, vascular, relation between pulmonary and systemic circulation in, 337
ASTHMA, urticarial, causation of hereditary

Auricular fibrillation, action of quinidine sulphate in, 1, 293
Auscultation sign of Richard Karplus, 482
AYRES, S.: Subungual verrucae, 304

B.

BARANOFF, M. V. : Changes in the amount of cholesterol in the blood in cholelithiasis, 454
BACQARIN, L. : Rare localizations of hydatid disease, 259
B. aertrycke, human infections with, 257
B. paratyphus B in the blood, the significance of, 219
B. suis infection 223
BAKMAN : The sex incidence of appendicitis, 100
Bacteriophage of d'Hercelle, the action of antidysoneric serum on lysie duo to the, 410
Bacteria, vitamins for, 200
BAHR, G. : Histopathology of filter-passing virus of influenza, 370
BALDWIN, L. : Vaccino therapy in oto rhinology, 339
BALDOZZI, O. : Voluntary diplopia, 317
BALIANTINE, J. W. : Fœtal post-maturity, 194
BALSAMO : Methods of drainage in surgery, 278

BANO, S. : Aspirin in asthma, 186
BANESILLON : The rapid diagnosis of urinary tuberculosis, 22
BARNI, A. : Mental disorders in epidemic encephalitis, 480
BARNI, H. : The importance of hereditary syphilis in infantile atrophy, 273
BARD, L. : Physiology of the sympathetic nervous system, 271
BARRENSHOEN : A new reaction for urea and its clinical value, 23
BARTLETT : Indications for splenectomy in children, 31
Basophilic inclusions in polymorphonuclear leucocytes, 369
BAUDY, M. : A new method of isolation of the tubercle bacillus from the sputum, 474
BAUER, A. W. : Glycosuria in pregnancy, 468
BAUER, J. H. : Tetanus bacillus in intestines of man, 327
BEAUMONT, W. M. : Butyn as a cocaine substitute, 125
BECK : Indications for Caesarean section, 16
BÉGUIN, P. : Necrobiosis of myomata, 175
BEHNER, A. : The Schick reaction in an epidemic of diphtheria, 475
BELAI : A new typhus organism, 160
BERRLINGER, W. : Acute leukaemia, 225
Beri-beri, post-operative, 341
BERNHARD, P. : Intravenous injections of calcium in congestion of the lungs, 397
BESSEMAN, A. : The effect of antidiaphtheritic vaccination, 220
BESSON, A. : Human infections with *B. aertrycke*, 267
BEUTER, AV. : Vaccines in osteomyelitis, 338
BEZANCON, F. : Necrotic dissecting pneumonia, 245
BICKEL, G. : Is tuberculous meningitis curable? 433
BIGNETTI : Serological test for cancer, 45
Bismuth poisoning and albuminuria, 315
Bismuth preparations in treatment of syphilis, 392
BLASCHKO : Dermatitis from dyed furs, 2
Blashtomycoses, pulmonary, 276
Blashtomycosis, systemic, 310
BLOCH, M. : Influence of antityphoid vaccination on the enteric fevers, 520
BLOCH, F. : Treatment of syphilis with bismuth preparations, 392
BLOCH, F. : Vaccines in influenza, 206
Blood, *B. paratyphus* B in, significance of, 219
Blood cholesterol in syphilis, 182
Blood coagulation during pregnancy, variations in the time of, 452
Blood elements, metabolism of, 157
Blood nitrogen in surgical lesions of the kidney, 381
Blood, pathological significance of abnormal leucocytes in, 348
Blood picture of radiologists, 431
Blood pressure, high, the adrenalin reaction in cases of, 68
Blood pressure, high, myomata and, 448
Blood pressure, high, without renal disease, 92

Blood sugar, effect of the removal of the liver on, 183
Blood transfusion, 60
Blood transfusion and the treatment of anæmia, 170
Blood, venous and capillary, relationship between the leucocytes of, 161
BLOOMFIELD: Significance of influenza bacilli, 21
BLOOMFIELD, A. L.: Bacteriology of the mouth, 201
BLUM, Paul: Bismuth poisoning and albuminuria, 335

British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, JULY 1st, 1922.

A British Medical Association Lecture ON THE MODERN TREATMENT OF SYPHILIS.

BY
L. W. HARRISON, D.S.O., M.B. GLAS., M.R.C.P. EDIN.,
DIRECTOR, VENEREAL DISEASES DEPARTMENT, ST. THOMAS'S HOSPITAL.

MAY I be pardoned for starting my address with the truism that our primary object in treating syphilis, to be kept always before us, is to rid the patient of *Spirochaeta pallidum* without poisoning him with the remedies employed. Before discussing the present-day treatment I should like to hark back to the days immediately preceding the introduction of "606." I do so because I think that some of the lessons we learnt then are apt to be forgotten to-day.

In 1909 we were relying for the treatment of syphilis mainly on mercury and iodides, and many of us found it a task which was full of disappointments. Frequently the patient relapsed whilst actually under treatment; frequently he displayed signs of intolerance in the form of stomatitis or albuminuria whilst showing active signs of syphilis, and no small ingenuity had to be displayed in steering many of our patients to recovery. At that time it was generally considered in this country that two years' treatment sufficed for most cases, though in some other countries four, five, or even more years were regarded as the minimum. Syphilologists in this country were beginning, however, to realize that two years' mercurial treatment carried out on lines that are practicable for the multitude was not sufficient for the average case, and I was able to show by Wassermann tests on over 400 soldiers, only three months after completion of two years' injection treatment, that over 40 per cent. were positive to the original test and over 70 per cent. to Stern's modification. These facts regarding the comparatively feeble effect of mercury and the insufficiency of two years' treatment by injections of mercury have certainly influenced my own attitude towards the place of mercury in the treatment of syphilis, causing me to continue the use of arsenobenzol remedies far beyond the stage when many workers suspend them.

In 1910 we saw the introduction of arsenobenzol compounds, and with it a revolution in antisyphilitic treatment, which is not yet over. The initial effect of "606," which, to us who were accustomed to relying on mercury only, seemed almost magical, accounts for a period during which large numbers of syphilitic patients were undertreated. When we saw lesions which had resisted our most carefully planned attacks by mercury disappear in a week or so after a first injection of "606," when we saw that spirochaemes had disappeared completely from the secretions of lesions in twenty-four hours or less, it was hard to resist the temptation to believe that here at last was the long-sought one-dose cure of syphilis. We learnt our error when we saw cases of syphilitic meningitis becoming much more frequent, chiefly in the form of cranial nerve paralyses, and since then we have been increasing gradually the period of treatment until, in many quarters, it has now become the two years of pre-salvarsau days.

At Rochester Row we carried out an investigation to discover the minimum amount of arsenobenzol and mercurial treatment required to cure an average case of early syphilis, and at the outbreak of the war we had arrived at the conclusion that a course consisting of one dose of 0.6 gram "606," five 1-grain doses of mercury, another dose of 0.6 gram "606," five more doses of mercury, and a final dose of 0.6

gram "606," was insufficient treatment, as it had been followed by about 25 per cent. of serological and clinical relapses within a year of suspension of treatment. We had learnt—from other workers' experience, I am glad to say—that if doses of 0.6 gram "606" are repeated too frequently, a certain toxic effect of "606" was apt to become uncomfortably frequent—namely, epileptiform convulsions, coming on within five days of the injection and often ending fatally. The pathology of this "encephalitis haemorrhagica" is a widespread thrombosis, or partial thrombosis, of cerebral capillaries, followed by multiple capillary haemorrhages. Some cases show also evidence of similar damage to renal capillaries, and the tubules are found to be packed with red blood cells. You will find in the literature that this is the chief bugbear of the German syphilologists, and is no doubt the reason for the recent edict of the Deutsche Reichsgesundheitsamt that a single dose should not exceed 0.4 gram "606."

My task in the war seemed at first only to devise a treatment which would enable us to increase on our pre-war treatment in the matter of dosage and yet decrease the length of the course without giving rise to a large percentage of "encephalitis haemorrhagica" and "haemorrhagic nephritis." So I split the doses, and at first gave eight doses of 0.3 gram "606" in twenty-eight days, with mercury. The event more than justified my hope that we should largely avoid encephalitis by this plan, because very few cases were recorded in the whole war, but we began to see other toxic effects which I had never witnessed before—namely, dermatitis and jaundice—and it can safely be said that these are the main toxic effects which we have to fear from arsenobenzol treatment to-day. It is true that we have also to reckon with vasomotor disturbances coming on during, or very quickly after, injections, but these, though sometimes alarming, are seldom, if ever, fatal.

Jaundice and dermatitis have certain features in common. Both are apt to be fatal, and both may appear long after a course of injections has been given—dermatitis as long as three months, and jaundice even twelve months later, though either may commence at any time during the course. It was this incubation period which caused me to introduce intervals of ten to fourteen days into the course of treatment, in the hope of catching the susceptible cases before too much arsenic had been given, and the course was lengthened first to forty-two days; then to fifty, and lastly to fifty-seven days. The result was that, by the end of the war, the incidence of both dermatitis and jaundice had become almost negligible in the military hospitals in this country. We learnt also that, if every patient is watched carefully during the course of treatment, and the injections are stopped on the first signs of an erythema, the incidence of severe dermatitis is very considerably reduced. Sicard has drawn attention to a sign of skin intolerance which I think may prove of some value. This sign is a patch of erythema provoked by the iodine which is painted on the bend of the elbow before the injection, and visible when the patient is about to be injected again. Sicard also considers that loss of the tendo Achillis jerk during the course of treatment is a sign that the patient is becoming poisoned by the arsenobenzol. Dermatitis has become much less frequent since the war, and I think it is because our patients are under less exposed conditions. I learnt quickly in Franco that dermatitis is much more severe in winter, and that, as soon as it commences, the patient must be protected, or he will die of pneumonia.

Jaundice, on the other hand, has become more frequent. At first I thought jaundice of no great moment, but two outbreaks in military hospitals in this country in 1917 and early 1918 made me think much more seriously of it. In one

hospital fifteen cases died in about nine months of acute yellow atrophy, and in another, three in about three months. The cause of these outbreaks is still rather obscure. They have been noted elsewhere, and have seemed to bear no relation to any change in technique or remedy. At first I thought acute yellow atrophy to be a liver disturbance of a different order from the liver disturbance we find in ordinary cases of jaundice following arsenobenzol treatment, but the evidence seems to point at present to the two types depending on liver poisoning of different degrees of severity. It is still uncertain whether this jaundice is due entirely to arsenobenzol, or whether there is another factor, either predisposing or precipitating. It seems strange that it should occur in small outbreaks if it is entirely due to arsenobenzol, and, just as in trinitrotoluene poisoning, which it resembles very closely, the theory of an intervening factor is very tempting. There is no doubt, however, that arsenobenzol does cause hepatic inefficiency, as Mackenzie Wallis at St. Bartholomew's Hospital and Spence and Brett at St. Thomas's Hospital have shown by the laevulose blood sugar test, and this inefficiency persists for as long as three months after a course of injections. The resemblance of what I may call arsenobenzol poisoning to that seen in the war amongst workers with T.N.T. has given rise to the idea that it is not due so much to the arsenic as to the organic complex of arsenobenzol.

Whatever the true etiology of jaundice, I am convinced that there is a relationship between the intensity of arsenobenzol treatment and the incidence of jaundice, as Bolam pointed out at the British Medical Association Annual Meeting in 1919, and it is on this that I have framed the course of treatment which I advocate for different types of syphilis. MacLean has suggested that empty liver cells are more likely to take up arsenobenzol than full ones, just as the livers of starving puppies are poisoned by chloroform and those of well-fed ones escape. It may be confirmatory of this theory that one's private patients do not seem to develop jaundice on the same course of treatment as that given to clinic cases. It is possible that this is due to the fact that the liver cells of the well-to-do are better fed and less likely to take up the poison, and it may be that we go too far in the number of hours we make our patients fast before injections. On the suggestion of Professor MacLean we have for some months given our female patients at St. Thomas's Hospital a drink containing 2 ounces of glucose half an hour before each injection. It may be a coincidence, but it is worth noting that since we adopted this practice nearly a year ago the jaundice in this department has become negligible.

I should like now to explain the line of treatment I adopt in average cases of syphilis of different ages of infection with reference to the tables which I have put up on the wall.

603-623 ...	Potassium iodide.
624-749 ...	Rest.
750-781 ...	Course of 5 as in "B" 4.

First, as to the various terms. In the "606" class we have an array of preparations known under various names, as follows: Salvarsan, arsenobenzol, arsenobillon, kharivan, diarsenol, arsphenamine, etc. They are all dioxidiamido-arsenobenzol dihydrochloride, and require alkalization before use; they upset the patient more, but give much better therapeutic results than "914." They are not very popular for private practice and outdoor patient work because of their inconvenience.

The "914" class, chemically dioxidiamido-arsenobenzol monomethylene sulphoxylate of soda, known as follows: Neo-salvarsan, novarsenobenzol, novarsenobillon, neo-kharivan, neo-diarsenol, neo-arsphenamine, etc. They are very convenient, because they can be given in comparatively small bulk and cause much less disturbance, and are therefore universally popular. Their disadvantage is that, when given intravenously, their therapeutic effect is less than that of "606." Closely allied is sulfarsenol, a preparation which has the great merit of causing little pain when given subcutaneously or intramuscularly. It is a preparation which I use greatly in private work, and one which has stood me well in cases with what is called an inveterate Wassermann reaction. I have always maintained that the subcutaneous injection of an arsenobenzol compound gives a better therapeutic result than if the same dose is given intravenously. The subcutaneous injection has the further advantage that it can be given without reference to a meal. The immediate toxic effect is also less, though animal experiments show that the lethal dose, as well as the curative, for animals is reduced by subcutaneous injection. Silver salvarsan is a combination of sodium salvarsan with silver, and appears to be twice as

powerful in equivalent doses. I have found it very useful in cases of tabes and other syphilitic diseases of the central nervous system.

Mercury I prefer to give in the form of mercurial cream or as salicylate by intramuscular injection, because it acts better than when given by the mouth, and injection is more convenient than inunction.

You will see from the table that I have divided my cases into different types:

- Primary cases with negative Wassermann reaction.
- Primary cases with positive Wassermann reaction.
- Secondary cases.
- Later or old-standing cases.
- Nerve cases.

The treatment prescribed increases with the age of the infection. The scheme on which the unit course is distributed is very similar in all but the nerve cases. The start is with three moderate doses; that is to avoid encephalitis, of which I have personally seen only two comparatively mild cases. There are various gaps after the third, fifth, and seventh injections. These are in order to give susceptible cases a chance of showing signs of intolerance before too many injections have been given. I may say that in my clinic at St. Thomas's Hospital the skin and mucous membrane of all patients are examined and the urine tested before each injection, and to that I attribute our comparative immunity from serious toxic effects. The same routine was adopted, with similarly happy results, in my hospital in France and at Rochester Row as soon as it was realized how easy it is to overlook such signs of intolerance as slight erythema and to pile fuel on fire by giving more injections.

At various points a course of iodide is given; that is in the belief that iodide assists the resolution of the process. I conceive the unit syphilitic lesion as a colony of spirochaetes surrounded by a wall of more or less fibrous tissue, and so protected from agents circulating in the blood. I regard the iodide as an agent which will stimulate the tissues to break down that wall and let in the antisymphilitic remedy to the spirochaetes within.

The minimum treatment proceeds far beyond the stage when the Wassermann reaction has become negative. Many workers consider that, when the Wassermann reaction has been rendered negative, treatment may be suspended, or at least mercury can be relied upon to complete the cure. This implies a belief that, when the Wassermann reaction has been rendered negative, the germ of syphilis has been almost eradicated. I should like to contest this view, because if it is not correct thousands of syphilitics are to-day being treated insufficiently and will remain syphilitic to the end of their lives. It is useless to say that, if the initial treatment is insufficient, the error will be corrected when the patient relapses. All of us know quite well that a large proportion of insufficiently treated cases do not relapse with clinical signs but only serologically. We know also that, so long as no outward signs appear, very many patients do not trouble to come for blood tests, so that the serological relapse goes undetected for months, if it is ever discovered. I would remind you that the skin and mucous membranes are not the only parts of the body in which the germ of syphilis flourishes and that a patient may be a public danger as well as a candidate for future dependence on the charity of his friends and relations, though he may have shown no outward signs of syphilis for years.

With regard to the negative Wassermann reaction as a guide to cure, nobody knows how much spirochaetal activity is required to produce a positive Wassermann reaction. We know that it varies in different patients, and there are some who may show such gross outward signs of syphilis as a papular eruption, mucous patches, and condylomata, and yet give a negative reaction, and we know also that very many patients who have been treated only until the Wassermann reaction has become negative subsequently relapse, proving that the germ of syphilis was by no means eradicated by the time the reaction first became negative. Altogether, therefore, although nobody knows how much devilry is going on behind the veil of a negative reaction, everybody knows that it may be considerable, and I contend that we are not justified in assuming either that treatment may be suspended when the Wassermann reaction first becomes negative, or that it may safely be continued with mercury only to complete two years. I have given reasons for showing that mercury given for two years, administered in the only forms which are practicable for the multitude, leaves a high proportion of cases uncured, and I hold very strongly that every remedy at our disposal

should be employed in the continuation treatment. The amount and length of the continuation treatment should, in my judgement, be that which observation in the past has shown to result in no relapses after prolonged suspension of treatment.

I do not believe in being guided by the progress of the patient, except, of course, as regards signs of intolerance of treatment. That policy means giving a certain amount of treatment, which in some cases has apparently resulted in cure but in others has been followed by relapse, and then watching to see how it works in this particular case. If the patient does relapse he is in much worse case, and often by this time he has passed the disease on to some other person. It is not in this way that we shall eradicate syphilis. Most of the cases of syphilis we are treating to-day are under our care because of the introduction of a public health measure which aims to stop the spread of this disease by rendering the greatest possible number of persons permanently non-infective. It is not merely the hiding away of a sore, a rash, or an ulcerated throat, or even the rendering of the patient temporarily non-infective, but the stopping of any further chance of that patient passing on the disease to others. If we merely introduce an interval of a few months of non-infectivity we are not fulfilling the public health ideal; in fact, the money spent on the treatment of the patient is largely wasted. Lastly, in favour of my plea for a treatment which does not stop until there are very strong reasons for believing that the disease has been eradicated, I would suggest to you that it is nothing less than this which would satisfy any of us if we were so unfortunate as to contract syphilis.

The plan I have laid down for later cases consists of a number of short courses. Many hold that it is useless treating an old-standing case with a positive Wassermann reaction beyond the stage when the symptoms have gone. They say that the Wassermann reaction will never be changed however much treatment is given. This is not correct; if the treatment is prolonged the reaction often does become negative, and the gradual change can be watched if the strength of the reaction is titrated out. Some ask, What, after all, does a positive Wassermann reaction matter? Many hale and hearty men, they say, have a positive Wassermann reaction and are none the worse for it. Other workers hold that a positive Wassermann reaction in late cases signifies only that the patient has at some time suffered from syphilis, and that it does not spell present activity of *Spirochaeta pallidum*. If so, I would ask why the reaction diminishes in strength and may die out under prolonged treatment, and the patient's general health improves in the process. I do not agree that a positive Wassermann reaction is a trifling sign. If the apparently hale and hearty person with a positive Wassermann reaction is examined critically he is often found not to be so hale and hearty as he appears to a casual observer. He is of the type who drops down dead or begins some day to talk nonsense and act irresponsibly, and I agree with Stokes, who says that those who regard a positive Wassermann reaction as indicating nothing more than a high resistance should at least submit their cases of the kind to expert clinical examination before continuing to hold that belief. He found that such an expert examination disclosed a high percentage of disease, particularly cardiac and nervous, and I would again remind you that the skin and visible mucous membranes are not the only parts of the body on which the germ of syphilis acts. It is my experience that very many patients with a strongly positive reaction say on commencing treatment that they feel all right in themselves, but the same patients remark at a later date that they feel fitter now than they have done for years.

For nerve cases the course outlined shows a frequent repetition of small doses, preferably of silver salvarsan, which seems to act particularly well in getting rid of the lightning pains of tabes. Although the course commences very mildly you will see that the total amount administered is not small, and it is wise not to allow too long an interval between courses.

If general paresis be excepted I think the outlook for nerve cases is generally good, provided that the treatment is instituted fairly early, and I have had excellent results in tabes from long-continued arsenobenzol, mercurial, and iodide treatment. General paresis is a different matter, and I think that most workers are pessimistic regarding the outlook in these cases. Since the present prognosis is so hopeless, and any measure which offers a glimmer of hope is justifiable in general paresis, I may perhaps be pardoned for relating a case of my own in which I think that treatment has definitely

influenced the course for the better and has certainly had a profound effect on the serum and fluid reactions. It shows also the extraordinary amount of arsenobenzol which some patients may receive without apparent ill effect.

This patient came under my care in June, 1921. He had then been in a private asylum for eight months, with typical signs of general paresis. The history of syphilis dated to about thirty years previously.

lips, Argyll serum react positive. T it Rombergism. The blood fluid reactions were strongly contained 250 cells per cubic millimetre, and the globulin content was marked. He had recently received seven injections of "914," and this treatment had then been abandoned as no improvement had resulted. I was asked to do anything which offered the slightest hope of cure, regardless of risk. I stipulated that treatment should not be abandoned unless no improvement had followed at least twenty arsenobenzol injections. I decided to combine injections with spinal drainage. The treatment and progress were as follows:

From July 3rd to July 31st, 1921, I gave 1.5 gram silver salvarsan in seven intravenous, and 0.6 gram salvarsan in two intramuscular injections, and drew off 140 c.cm. of cerebro-spinal fluid by three punctures. The patient then refused all further treatment, and showed generally no improvement; if anything he seemed slightly worse than when treatment commenced. During August and September he improved sufficiently to cause his wife to press for his removal to his home, where the further treatment has been carried out. Treatment was resumed on October 1st, 1921, when he was fairly quiet, though delusional on certain matters, such as religion, and grandiose on money matters. The cerebro-spinal fluid gave a strongly positive Wassermann reaction, but the cells numbered only 6 per cubic millimetre.

From October 1st to November 26th, 1921, I gave him 3.2 grams of silver salvarsan in seven injections, ranging from 0.3 to 0.6 gram, and drew off 275 c.cm. cerebro-spinal fluid by seven punctures. Under this treatment he improved very considerably, shedding much of the general paretic mental outlook and behaviour. The Wassermann reaction of his spinal fluid became weaker, giving a reaction only in a dilution of 1 in 2.5 and higher concentrations, and the cells numbered 2 per cubic millimetre. Lange's gold test, however, gave a strongly marked paretic curve. Treatment was suspended from November 26th, 1921, to February 18th, 1922, and it was interesting to observe how he relapsed gradually during the last month of this interval, becoming more and more general paretic, until at last he was quite as bad as on his first return home. I decided to push the treatment far more intensively, and from February 18th to April 4th, 1922, I gave 8.55 grams silver salvarsan in ten injections, ranging from 0.6 to 1.25 gram, and drew off 220 c.cm. spinal fluid by six punctures. The injections were well tolerated, mainly, I think, because they were given in 7 per cent. glucose, and 2 oz. glucose were administered by the mouth one hour before each injection.

The clinical improvement under this treatment has been most marked, and he is now more nearly normal than he has been since he was certified as insane about a year ago. He can criticize a book as intelligently as before his illness commenced and write a sensible letter with no omissions. His balance, formerly very unsteady, is now firm and he walked fifteen miles a few weeks ago. His conversation is generally rational and his memory good, but he is still rather delusional on religion and Christian Science. The improvement in his house manners is particularly marked. He is normally very considerate for others, but in the relapse preceding the last behaviour, after the treatment was resumed his normal refinement of behaviour gradually returned. His fluid now contains 1.3 cells per cubic millimetre, gives only a partial Wassermann reaction

with one whole volume, and the gold-sol reaction is definitely weaker. The blood-serum reaction is now negative.

[Note on Correction, June 11th, 1922.—This patient is now normal in behaviour under all conditions, except in regard to the healing powers of Christian Science, in which he is definitely more optimistic than the average adherent of that faith.]

Of course, remissions occur in general paralysis of the insane without treatment, as everyone knows, but in this case it is difficult to attribute the second improvement, dating from the commencement of the last course and proceeding steadily to the end of it, to any other cause than the huge doses of silver salvarsan administered. The case is incomplete, but has proceeded far enough to show that colossal doses of silver salvarsan do affect adversely the deeply buried spirouemes in general paresis, and that is my excuse for relating it at such a comparatively early stage.

THE PLACE OF OPHTHALMOLOGY IN THE UNDER-GRADUATE MEDICAL CURRICULUM.*

W. GORDON M. BYERS, M.D.,
MONTREAL.

"In education, most time is to be bestowed on that which is of the greatest consequence in the ordinary course and occurrences of the life the young man is designed for."

LOCKE.

WHAT part of ophthalmology shall be taught in the undergraduate medical course? How much time shall be devoted to the subject? These are important questions; for in seeking to determine the place of ophthalmology in the undergraduate medical curriculum one is faced at the outset, not only with the problem of what to do with the specialties in general, but also with the whole problem of undergraduate medical teaching.

A great deal of time and thought has been advantageously devoted in recent years to the subject of post-graduate ophthalmic studies, but apparently very little by comparison has been given to the work. The reason probably is that the prescient circumscribed field that falls largely to teachers in the specialties for solution, while undergraduate studies in any one subject are but a single factor in a much larger problem, in which workers in all the branches of medicine are interested.

It seems a duty for ophthalmologists to take part in the widespread deliberations that are shaping the policies of all medical schools; especially so as some of the proposals that have been made in regard to the disposition of special studies are obviously founded upon a misconception of values and of the primary purpose of undergraduate medical education.

Before beginning the study of the problem we must set clearly before ourselves exactly what we wish to accomplish in undergraduate teaching. We still touch hands with those for whom it was possible in their college years to gain a fairly comprehensive grasp of the whole range of the medical knowledge of the time; but the phenomenal development of medicine during the last few decades has made this less and less attainable. Students are now forced to confine themselves to phases of the old major subjects, to subjects of recent development, and even, again, to ramifications of them. We have, in a word, witnessed an extraordinary development of specialization. The problem of undergraduate work is to-day, therefore, much more complex. Men aim not at one goal, but aspire to varied fields of endeavour.

As a starting point we must classify students in accordance with what they have in view. This is not a difficult matter, for quite simply our students fall into three groups: Those who are destined to be general practitioners; those who will be clinical specialists; and those who will specialize in research, teaching, and public health.

The specific business of the general practitioner is to treat sick individuals—in other words, to grapple with distinctive medical problems. Some of these problems are of little or no moment; others are of vital importance; and many of them are clearly beyond the scope of the general practitioner. It is obvious that in order to see clearly what are the requirements of the general practitioner in the way of instruction and training, we must set forth his problems and make some kind of classification in accordance with their relative values.

Clearly, the only standard of classification one can adopt

* Read before the American Ophthalmological Society, Washington, May 2nd, 1922.

in this field is the hearing problems have upon the preservation of life and of function. On this basis medical disorders can be instantly separated into those that menace life and those that do not. Disorders that do not menace life can be subdivided into disorders which threaten complete and permanent disablement and those which do not. The first subdivision (disorders which threaten complete and permanent disablement) includes two sets of conditions: those which call for immediate recognition and immediate and effective interference, and those which do not. The second subdivision (disorders that do not menace life) embraces three classes: those which involve temporary disability but tend always of themselves to recover; those which do not involve temporary disability but cause discomfort in varying degree and lower efficiency; and those falling in the field of congenital deformities and cosmetics.

Although this classification is not intended for more than a suggestion, it yet suffices to throw into relief the relative importance of the disorders by which the general practitioner may be faced. But the classification covers the whole range of the problems of medicine and surgery; and since no man can at this day hope to master the entire subject, it must be determined which part of it the general practitioner can reasonably be expected to manage.

It is evident that the foremost place must be accorded to those disorders that carry with them a menace to life—namely, haemorrhages, suffocations, serious fractures, strangulations, virulent infections, poisonings, and cancerous growths. Scarcely less important are the conditions that lead to complete and permanent disablement, that deprive a man of his active life in society. No one will question the assertion that this state is regarded by mankind as among the great tragedies of life. Under these two headings are what may be called the major problems of medical practice. These problems vary in their degree of urgency, but they demand of the practitioner a knowledge so complete that it will express itself in immediate and fully effective action. Delay and partial recognition mean death and disaster.

On the other hand, it is equally clear that in a field that cannot in any event be fully covered the disorders that do not threaten complete and permanent disablement are those which should receive least consideration. At their head stand those conditions which are either extremely rare or require for their management a training beyond the power of the student to acquire. These belong of necessity to the province of specialization. If we eliminate these, as we reasonably must, we reduce the problems of our second division to a group made up largely of what we may call the minor ailments—that is, disorders which are neither menacing, complex, nor rare, but assume a certain importance because of the frequency with which they occur. In this minor field, then, and in the major field of menacing disorders, lie the problems that fall with reason to the general practitioner.

The segregation of his problems in this way reveals the educational requirements of the general practitioner. A distinctive problem in the field of practice implies in a broad sense a distinctive scholastic task. We are able, through our classification of medical disorders on the basis of what is of most importance, to design an undergraduate curriculum in accordance with the principle of what is of most worth. This principle requires, on the one hand, that the range of problems as determined shall shape the studies underlying their comprehension, and, on the other, that the amount of time and attention given to the mastery of a problem shall be proportionate to its importance as fixed. Major problems must always take precedence over minor problems, to the extent of entire neglect of the latter, if time be limited.

What applies to the design of the curriculum as a whole applies to the individual studies. This answers the question as to what part of the subject shall be taught. The time devoted to a subject is to be determined in accordance with this decision. The place of a subject in the undergraduate medical curriculum—the place of ophthalmology, for example—will be proportionate to the number and character of the problems which fall to it from the whole number as determined. These conclusions lead us to see how illogical is the practice of devoting an equal amount of time to the specialties simply because they are so classified, instead of apportioning time on the basis of relative values. They also dispose of the proposal that the specialties as such should be entirely eliminated from the undergraduate curriculum, to the end that the whole time available may be devoted to the major subjects.

To illustrate of what has been said let me indicate the

disorders that must shape the undergraduate course in ophthalmology for general practitioners.

Major Problems.

1. Disorders that menace life: intraocular tumours; malignant growths on and about the eye; wounds and injuries; orbital cellulitis and osteitis from extension or from metastasis. The student should have knowledge of, and be able to distinguish between, the various disorders of which exophthalmos or proptosis is the most striking sign.

2. Disorders that do not menace life but are signals of disorders that menace life: optic neuritis, or "choked disc"; the various types of systemic retinitis and choroiditis; paralyses of the intrinsic and extrinsic muscles of the eye; visual disturbances expressive of disease in the optic tract.

3. Disorders that threaten complete and permanent disablement and call for immediate recognition and immediate and effective interference: the purulent ophthalmias; trachoma; pterygium rarely; phlyctenular conjunctivitis; tuberculous and diphtherial conjunctivitis; ulcer of the cornea; interstitial keratitis; wounds and injuries and burns of the eye, including foreign bodies, or the field of industrial accidents; iridocyclitis; panophthalmitis; sympathetic ophthalmia; glaucoma; optic neuritis, of local origin, or axial; dacryocystitis; myopia.

Minor Problems.

Sties; chalazious; marginal blepharitis; chronic catarrhal conjunctivitis.

It will be noted that, apart from numerous other harmless and rare conditions, one excludes from this list almost the whole series of cataracts and congenital anomalies. Implied, too, is but a limited acquaintance with the subject of muscular anomalies, and the operative field is highly restricted. On the other hand, the work demands a fair mastery of refraction, ophthalmoscopy, and perimetry in the functional examination of the eye.

If we were dealing solely with the ophthalmic course the problem of how to present this work would not be difficult; but in undergraduate teaching we must view the matter from the standpoint, not of one but of all the subjects composing the undergraduate curriculum. Admitting that at the moment, and still more in the future as medicine develops, problems from the field of general practice must fall into the fields of specialization, when we come to include all that bear on general practice we are confronted by what is apparently a task of great magnitude. Nevertheless, this principle of what is of most worth leads us to conclude that at any given time the maximum feasible achievement in the field as outlined shall be the minimum requirement in the way of a curriculum for general practitioners.

Now professedly the colleges undertake to cover this field; but we know only too well how far they fall short of meeting the requirements—that there are annually graduated in large numbers men who are quite incapable of overtaking what should reasonably be expected of them in the field of general practice. I shall not now occupy time with an analysis of the causes of this lack of success. Mainly it has been due to failure in recognizing the diversity of aims that has arisen, to efforts that have been made to develop unduly the purely educational aspects of medical studies, as well as to the introduction of "cultural" subjects that are clearly outside the province of a medical curriculum. The consequence of this confusion of ideals has been to graduate men on the one hand with an inadequate knowledge of important problems and of the subject as a whole, and on the other hand with an unnecessary knowledge of minor problems and of things outside the practitioner's field. Because of the insuperable difficulties of the curriculum practical training has been neglected, facts have usurped the place of principles, and knowledge the place of education.

The consciousness of failure is a matter of concern and dissatisfaction to teacher and graduate alike; but behind the faculties and behind the practitioners is a third group whose interest in this matter has been apparently overlooked. In the end, medical education is a trust imposed on the schools and colleges of the country by the public, and one does not need to put one's ear close to the ground to learn that there is discontent with the manner in which practitioners are being trained to deal with the emergencies that arise in the community. From every point of view, therefore, the situation demands redress.

A curriculum designed in accordance with the decisions that have been reached offers a helpful measure for the solution of the difficulties. Taking the practitioner's problems as listed we shall develop courses of study that will cover as nearly as possible, not only the field as a whole, but what the student is expected to know of each individual problem. It is implied that at the beginning of each course the student

shall be given printed notes or a synopsis of the work to be done. Assistance may be had from the different departments; but in the end everything is to be carefully considered and brought into conformity with a prearranged plan. This work ought really to be entrusted to a small group of men, vested with considerable authority; and I suggest that it would be helpful for them to think of the problems, not as belonging to the various fields, but rather to medicine and surgery—to the mother subjects—as indeed they do.

Particularly important is the fact that under a unified direction it would be possible through co-ordination to eliminate completely the wasteful overlapping that now prevails, as well in the primary as in the final subjects. This process should be extended to its logical limit, through subject and problem to phase and element. It ought to be determined at the outset, in every instance, when and by whom a subject of this kind is to be taught. Students should be required to master a problem as defined, once and for all, and having mastered it, pass to something else. On completion, the scholastic tasks would be distributed among the various subjects making up the curriculum. It really does not matter who does the teaching, though expediency would probably demand the services of experts in the special fields.

While what I have said applies particularly to the clinical subjects, which must be regarded as the basis for any arrangement of a curriculum, it also holds for the primary subjects; for the function of all primary teaching is to build concepts for the clinical work. The great fundamental principles will be taught as before; but with a classification of problems on the basis of what is of most worth, there will come to the primary teachers a scale of values that will be most helpful, as clearly indicating where emphasis should be laid in their work of preparation. It is not to be expected that all this could immediately be effected. Many difficulties can be foreseen. Adjustments and readjustments would be necessary; but eventually, with not one but many centres participating, there would develop a more or less standardized curriculum, which might be universally adopted.

But the adoption of a minimum medical curriculum implies certain specific obligations. One is, that the student must know everything of the subject as presented. It will not suffice that he recognize but two out of four essential problems, that he knew but half of what is expected of him to learn of any one problem. This suggestion demands a very thorough system of examination, under which accurate and continuous records are kept of the work the student has done and the success with which he has done it.

A second and equally important obligation is, that if a specified task is set the student, the subject must be fully and systematically presented to him. With exceptions, of course, clinical instruction in medicine is still largely and generally of a haphazard character and based on chance. By this I mean that in many clinics cases are used for teaching as they appear, without any thought of fitting them into a well-defined curriculum. The practice is largely the outcome of a want of clear conception of the field to be covered. The result is that the students either do not see examples of disorders with which they should be familiar, or that the subject may be presented a quite unnecessary number of times. All clinical teaching should, from the outset, be brought into strict alignment with courses previously defined. This second obligation has also a very important bearing on the existence of a college; for no school is justified in carrying on clinical teaching if the community in which it is situated is not sufficiently large to furnish clinical material of the right kind in adequate amount.

But if, in its application, the principle of most worth brings a more circumscribed, yet equally comprehensive curriculum, it demands, on the other hand, a more thorough practical training. Granting that the most is made of the facilities afforded by the dissecting room, the *post-mortem* room, and operative courses on the cadaver—and it is not—we are bound to admit that attendance on hospital work as now generally practised does not produce satisfying results. Training to be effective must be much more intimate. There is daily evidence of the rapidity with which graduate internes are trained to deal competently with problems that are entirely beyond the scope of the man who leaves college immediately to enter practice. We must strive to secure for our students similar facilities in their undergraduate years. The hospitals at present engaged in teaching could with advantage to the work of the institutions add greatly to the number of internes; but when the limits are reached a great field of opportunity for practical instruction remains.

Arrangements with non-teaching hospitals in college centres, as well as with numerous hospitals in centres which do not support colleges, could undoubtedly be made to share in the practical instruction of students. This means the training of the staffs of these institutions, who would then take rank as extramural teachers. The value of this enlarged opportunity for training to the colleges and to the student is apparent; and the benefit that would accrue to the community, through the raising of the standard of practice in this way, is scarcely to be estimated. The hospitals of the entire country might advantageously be utilized for this purpose. The suggestion implies in a broad and more modern sense a return to the old system of apprenticeship. Just how this idea would work out could not be determined until the curriculum as a whole had been developed. The main difficulty would be in arranging a plan of rotation. The housing problem would only be a matter of subsidizing the institutions to enable them to erect the necessary residences. Maintenance, in any case, would fall on the shoulders of the students.

More seriously to be considered is the objection that the work as outlined would occupy more time than men could afford. There is no reason, however, why theoretical instruction could not be concomitantly and even more advantageously carried on during the period of residence. Then, too, the time necessary to cover the field would be less than would first appear. Careful work in medicine paves the way for accurate diagnostic work in surgery, and the general training in surgical technique and the technicalities of the technique cover the whole field. Moreover, when one has mastered the major problems the minor problems present no difficulties.

Speaking for ophthalmology, I am satisfied that, to a man who has had a year of active work in general surgery, one could give a satisfactory training in the course as outlined for general practitioners in approximately four months' whole-time work, the necessary instruction in refraction and in ophthalmoscopy included. The ophthalmic operations falling to the general practitioner in accordance with the decisions formulated are few in number, including as they do only enucleation of the eye, excision of the orbit, drainage of the orbit, opening of lacrymal abscesses, sties, and Meibomian cysts, removal of foreign bodies from the cornea, cauterization of the cornea, and iridectomy for the relief of glaucoma and for incarcerated iris. The last mentioned is the only one that presents any difficulties, but these could be largely overcome by practice on dead animals' eyes.

But before estimating what, if any, additional period is necessary for practical training, note should be taken of the saving of time that can be effected in various ways for this purpose by the utilization of time that is still largely wasted in attendance on operative clinics, the details of which are entirely indiscernible; by the ruthless exclusion of everything that is obsolete and trivial and irrelevant; but most of all by a rearrangement of the present curriculum as I have suggested, as well as by the introduction of more effective methods of teaching and study that grow out of this work. In the last analysis the argument calls for a matriculation standard that shall be no more than adequate if time demands consideration.

A few final words about undergraduate optional courses and specialization are now required. Under the plan as outlined the scope of the curriculum would be much more sharply defined; and it ought to be possible, in a measure at least, to grade students and to permit the more brilliant among them to proceed to advanced work in optional courses after satisfying the faculties that they had mastered the information of a minimum curriculum.

But specialization in undergraduate years is unthinkable. The interdependence of the various systems of the body being so well established a fact, it is clearly impossible that a man could intelligently practise in any special field without a knowledge of medicine and surgery as a whole. The only guarantee against narrowness of view, the bane of specialization, is a broad theoretical training. On the other hand, a general surgical training is the corrective for meticulous and careless methods in the special operative field.

Finally, from the point of view of public necessity—and that must always be the last court of appeal—it is not to be tolerated that men trained in limited fields of medicine shall be given the right to practise the art as a whole; for there is no guarantee that men so trained will always succeed, or that later they may not wish to establish themselves as general practitioners. The only conclusion is that men must qualify fully as physicians and surgeons before becoming specialists.

THE DIAGNOSTIC VALUE OF GASTRIC FRACTIONAL TEST MEALS.

BY

HUGH S. PEMBERTON, M.B., M.R.C.P.,

ASSISTANT PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

The following remarks are based on the examination of over two hundred fractional test meals undertaken during the last fifteen months. Nearly all these meals were withdrawn from patients presenting either symptoms or physical signs pointing to an abdominal lesion; other cases included persons thought to be normal and a few patients in whom the condition was definitely extra-abdominal.

The meal employed was that recommended by Ryle,¹ withdrawn by means of a Relifuss tube; the material withdrawn was filtered, and (in the filtrate) estimations of total acidity and of free hydrochloric acid were made by the Töpfer method. If the presence of bile was obvious search was made for it with the aid of acetone and nitric acid; microscopic examination both of the unfiltered gastric residuum and of the meal was also carried out. In a number of cases the chloride content was estimated by the Vollhard-Arnold method and hydrogen-ion concentration determined by the use of indicators. Correlation was also made, whenever possible, with clinical, radiographic, and verified findings.

Before setting out the actual findings, which are largely confirmatory of the work of others, it will perhaps be permissible to consider some points in relation to gastric secretion. Various views are held on the association between gastric secretory change and gastro-intestinal lesion, according to the supposed priority of one or the other event.² However this may be, it is certain that the amount of gastric secretion poured out in response to the stimulus of various substances introduced into the stomach is controlled to some extent by the operation of certain factors. The importance of one of these factors was emphasized by Boldyreff,³ who suggested an explanation for the fact that the acidity of fluid withdrawn from the stomach has not the same value (in terms of total titratable acidity) as that of freshly secreted fluid. In the light of recent and past investigations some of these factors which influence the time-acidity curve of gastric secretion may be summarized.

1. *Rate and Nature of Secretion.*—In the first place this must depend upon the amount of chemical or psychic stimulus brought to bear upon the gastric mucosa. By the use of uniform test meals given at the same hour the chemical stimulus may be presumed to be, roughly, of constant value; psychic effect can in some measure be avoided by careful manipulation of the Relifuss tube. Apart from these two factors, the rate and amount of secretion may be assumed to be a property of the particular gastric mucosa which is being examined.

2. *Rate of Evacuation of Stomach.*—It is this factor which, though not apparent in its influence in the earlier period of gastric secretion, is so largely effective in shaping the curve later on when the pylorus has opened sufficiently. Its effect on total acidity may be different from that on free hydrochloric acid content, as pointed out by Bennett and Venables.⁴ Taken alone, its most potent effect would appear to be exhibited in the time-acidity curve of the duodenal ulcer with hurry; its influence may also be inferred from the inspection of curves in cases of pyloric obstruction where this factor is obviously in abeyance.

3. *Rate of Neutralization or Dilution brought about by Regurgitation from the Intestines.*—It is evident that this factor must operate in association with the preceding one, since both depend upon the opening of the pylorus, except in cases of gastro-enterostomy or gastro-colic fistula. The existence of this factor may be demonstrated by the finding of trypsin or bile in the stomach;⁵ rate of dilution and rate of neutralization may be determined by total and inorganic chloride fractional estimations, as recently shown by Bolton and Goodhart⁶ amongst others. It would appear possible that the excessive operation of this factor might produce an achylia, complete neutralization being perhaps evoked by an original gastric hypersecretion.

Leaving out of account other possible but unknown factors such as the part played by the vascular system, some sort of general relationship may be formulated between the above and the acid concentration (total acidity) of the fluid withdrawn from the stomach. If C represent any point on the total acidity curve, S the rate of gastric secretion, E the rate of

evacuation, and R the rate of intestinal regurgitation, then it would appear that C varies directly as S and indirectly as E and R, or

$$C \text{ varies as } \frac{S}{E \text{ and } R}.$$

This relation cannot be considered as being in any way exact, because, although the associated factors E and R would appear to operate almost at once,⁷ it is certain that they reach higher values at a later period.

In the following six types, into which most of the curves obtained were divisible, an attempt has been made to interpret the shape and significance by reference to the above expression. Alterations in the factors S, E, and R are commonly found in association with gastro-intestinal or other lesions; it is legitimate, therefore, to assume that a curve expressing the shifting values of C, which itself varies with these factors, may show some specific relation with these same lesions. At the same time it must be admitted that such specific curves are by no means invariably obtained.

Curve Type 1 (Fig. 1).

This is the normal curve obtained by most observers—from Schülo in 1895⁸ to the present day. Here the factors S, E, and R would appear to have either fixed or balanced values, as it is obvious that the value of C would remain the same if there were similar increases in the values of S and R; this is, of course, the basis of the principle of automatic regulation advanced by Boldyreff.

FIG. 1.—Curve Type 1.
Case 139.

FIG. 2.—Curve Type 2.
Case 32.

In each of the figures the total acidity is represented by a continuous line, and the free HCl by a broken line.

Curve Type 2 (Fig. 2).

Known sometimes as the curve of larval hyperacidity (Hawth), this type has been associated with gastric ulceration; in my own series 83 per cent. of cases proved at operation to be of gastric ulcer gave this picture. It would appear that an originally high value of S is reduced later by a rise in the value of R, as shown by the entry of bile. In one case of gastric ulcer a curve of Type 6 was obtained, indicating perhaps an excess of the neutralizing factor; unfortunately no chloride estimations were made in this case.

Curve Type 2 can be taken therefore to indicate hypersecretion without much disturbance of normal gastric evacuation, a condition often present in ulcers of the lesser curvature.

Curve Type 3 (Fig. 3).

Here it is obvious that the value of E is so great as to lead to a rapid disappearance of recoverable gastric contents. High resting acidity is also a feature of this type of curve, as observed by Ryle⁹ and others; in my own series this picture with high resting acidity has been obtained in cases of duodenal ulcer, and, without high resting acidity but with a late rise in the inorganic chloride curve, after gastro-enterostomy. Out of seven cases of duodenal ulcer, a curve of this type was obtained in five instances, and of Type 5 in the remaining two.

FIG. 3.—Curve Type 3.
Case 30.

FIG. 4.—Curve Type 4.
Case 119.

Curve Type 4 (Fig. 4).

This is the type of curve usually present in cases of maintained pyloric obstruction, where it is obvious that the factors E and R can have little or no influence on the value of C; associated with this may be a raised or normal secretion value. In cases of malignant obstruction the high free hydrochloric acid curve may be absent, being replaced by an organic acid curve. This type seems to be of considerable diagnostic value, and is almost invariably obtained in severe grades of pyloric stenosis; all such cases in my own series gave this picture.

58	" "	Duodenal ulcer	Type 3	Duodenal ulcer.	142	?	? Pyloric stenosis; ? duodenal ulcer	Type 4	Simple pyloric stenosis.
61	" "	? Pyloric ulcer	Type 1	Gastric ulcer.	151	?	? Duodenal ulcer	Type 2	Ulcer near pylorus
67	?	? Prepyloric ulceration	Type 6	Mobile kidneys.	152	Pyloric ulcer	? Duodenal irritation	Type 4	Pyloric stenosis.

Curve Type 5 (Fig. 5).

This is the "climbing" curve or curve of tardive hyperacidity (Hawthorne), due presumably to deficient relaxation or spasm of the pylorus of a non-continuous type; this picture has also been seen in what can only be called idiopathic hyperchlorhydria, since no spasm or cause for spasm could be recognized. A great majority of these curves were, in my own series, associated with either small-pyloric ulcers (leading presumably to spasm), or with subpyloric conditions, such as appendicitis, where perhaps pyloric spasm was a reflex event similar to that observed in the experimental intestinal injuries of Cannon and Murphy. Removal of the subpyloric condition, which was postulated as a cause of the "reflex hyperchlorhydria" expressed by this type of curve, has, in my own series, been followed by an alteration approximating to Type 1.

Curves of this type were obtained in six cases which came to operation, and which exhibited lesions varying from a small pyloric ulcer to an inflamed appendix.

FIG. 5.—Curve Type 5.
Case 81.FIG. 6.—Curve Type 6.
Case 108.

Curve Type 6 (Fig. 6).

The so-called achylia curve, which may mean deficient secretion or early and complete neutralization, has personally been obtained in a variety of conditions which appear unrelated. These included normal cases and cases of gastric ulcer, gastric carcinoma, gall stones, movable kidneys, gastroptosis after gastro-enterostomy, and, in six instances, of exophthalmic goitre. There does not, therefore, seem to be any great diagnostic value in this type of curve, since it can be obtained in so great a number of conditions; on the other hand, it can serve as an indicator of the efficiency of the stomach when a gastro-enterostomy has been made.

From a general consideration of these curves valuable help in diagnosis would seem to be given, particularly by Types 2, 4, and 5. A comparison of this and other evidence with the actual finding as discovered by operation will, however, best illustrate this statement. The accompanying table shows that the fractional test meal method is worthy of comparison with the recognized method of opaque meals and x-rays. Forty cases have been taken at random; in each the clinical, radiographic, fractional test meal, and verified findings have been set out.

In concluding this note, I would wish to express my indebtedness to my colleagues at the David Lewis Northern Hospital for the provision of some of the clinical material.

Conclusions.

1. The acidity curves plotted from fractional test meal are of some value in obtaining knowledge of the factors which modify the acidity.
2. Alterations in these factors bear some sort of relation to lesions; hence the acidity curves may throw light on lesions.
3. These curves seem divisible into at least six types of varying diagnostic value.
4. By comparison with other methods the fractional test meal is at least admissible as an aid to diagnosis.

TREATMENT OF HUMAN HOOKWORM INFECTION
WITH CARBON TETRACHLORIDE.

BY

LUCIUS NICHOLLS, M.D., B.A. CANTAB.,

DIRECTOR OF THE BACTERIOLOGICAL AND PASTEUR INSTITUTES, Ceylon;

AND

G. G. HAMPTON, M.D.,

STATE DIRECTOR OF THE INTERNATIONAL HEALTH BOARD, ROCKEFELLER FOUNDATION.

In the *Journal of the American Medical Association* of November 19th, 1921, Dr. Maurice C. Hall, of the United States Bureau of Animal Industry, published a paper on the use of carbon tetrachloride for the removal of worms in animals. He stated that the results were satisfactory, and that almost all worms were removed by one dose. He recommended that 0.3 c.cm. should be given for every kilogram of weight of the animal. He tested the drug on monkeys, and gave two to five times this amount, and reported that no untoward symptoms ensued. Dr. Hall himself took in the morning 3 c.cm. of carbon tetrachloride, and afterwards did his usual day's work and was not inconvenienced in any way. He suggested that the drug would be valuable for the treatment of hookworm disease in man.

Several drugs are used at present for the treatment of this infestation, but all of them have disadvantages. Thymol and beta-naphthol, except in large doses, are ineffective, and are

difficult to administer to children, and occasionally deaths occur after their use.¹

Chenopodium has been used very largely in recent years, especially where extensive campaigns have been started among heavily infected populations in various parts of the tropics. It has those disadvantages:

1. It is objectionable to the patients.
2. It is frequently followed by depression, and it is necessary for the patient to remain at rest and away from work on the day that the drug is taken.
3. One day's treatment is ineffective with the majority of patients.
4. It is impossible to standardize chenopodium, which contains a large number of chemical bodies of unknown composition, and one sample of the drug occasionally is found to be more potent than another.
5. It is dangerous to administer to very young or very sick children.

Carbon tetrachloride, CCl_4 , can be prepared cheaply and in a high degree of purity. It is a colourless liquid with a sweetish, pungent taste, and it produces a slight sensation of burning when it is taken into the mouth. Its boiling point is 76.74°C . and its specific gravity is 1.63195. It is soluble in alcohol and ether, and will dissolve a large number of organic substances, especially those of a fatty nature. Previously it has been used in the practice of medicine as an anæsthetic and as an inhalation for hay fever. It was much used at one time as a dry shampoo, but it fell into disrepute because a woman, aged 29, died suddenly during its use for this purpose. Dr. B. H. Spilsbury stated at the inquest that the deceased was at the time of her death in a condition of status lymphaticus.² The preparation used by barbers would not be the chemically pure drug; and the commercial preparation contains two very poisonous substances—carbon bisulphide and carbonyl chloride, and as much as 2 per cent. of the former may be present.

Most fat solvents, such as chloroform, tetrachlorethane, or carbon tetrachloride, if they are inhaled for long periods cause subacute hepatitis, which may be followed by advanced fatty degeneration of the liver.⁴ But those effects do not occur after one or two doses of these drugs.

We decided to test this drug especially with a view to the treatment of school children and young children who are admitted to hospital with various diseases and who are also heavily parasitized by hookworms. One of us in association with Dr. Leach was the first to use the drug in Ceylon, and fourteen persons were treated for hookworm disease with doses ranging from 3 to 10 c.cm. The patients took the drug well and did not show the dislike to it that most patients show when chenopodium is taken. They did their usual day's work and complained of no untoward symptoms.

A murderer under sentence of death volunteered to take the drug, and 6 c.cm. were given one hour after the midday meal, and the same day he passed four worms (*Ascaris lumbricoides*); thirteen days later this dose was repeated at 7 a.m. before any food had been taken. The patient stated that at 11.45 he felt a little giddy and sleepy, but this soon passed. The execution took place a week after the second dose, and a post-mortem examination was done one hour after death. No hookworms or ascarids were found in the intestinal tract. Sections of his organs were examined microscopically, but showed no signs of degeneration of any kind. Therefore it is apparent that in single doses carbon tetrachloride is a safe remedy.

Next it was tried on the students of an agricultural school, who were from 18 to 25 years of age. A preliminary examination of samples of their faeces showed that all of them were infested with hookworms. No purgative was given on the preceding night. They all received a dose of 3 c.cm. of the drug at 6.30 a.m. before any food had been taken; no purgative was given after the drug was administered. They were instructed to carry on their usual mode of life, and restrictions were not placed upon their work, play, or diet. Not one of them was inconvenienced by the drug, and they all continued their day's work in the gardens or at the school house. They were supplied with "chatties," which were numbered, and they were instructed to pass their stools into these vessels. In this way all stools passed for three days after treatment were collected and carefully searched for worms.

A total of 719 hookworms, or an average of 36 for each student, were recovered. Besides these 13 *Ascaris lumbricoides*

+ = Plain smear positive for ova. (+) = Centrifuged deposit positive for ova. (-) = Centrifuge and salt flotation method negative for ova.

were passed. Microscopical examination of faecal specimens ten days after treatment showed ova of hookworms in only two specimens, which indicates that 90 per cent. were cured. Table I is a summary of this work. It will be noted that two-thirds of the worms were passed on the second day after the treatment.

Next the drug was tried on sixty-four male and female students whose ages were from 7 to 17 years. Samples of their stools were examined microscopically for the ova of worms: sixty were positive for hookworms and four were negative.

The method of examination adopted was to make smears from the stool, and if ova were seen this was signified opposite the number of the student by a *plus* sign; if no ova were seen a portion of the stool was stirred up in water and centrifuged; the deposit was smeared on a slide and examined, and if it was positive it was signified by a *plus* sign in brackets *plus* (+). If by this method it was negative, a remaining portion of the centrifuged deposit was stirred up in concentrated salt solution, for the high specific gravity of this causes the ova to float to the surface; when a slide is brought into contact with this surface the ova will adhere to it. This is known as the "salt flotation method," and when stools contain so few ova that this method must be used to reveal them the result is signified by a *plus* sign in brackets and an asterisk thus (+)*. When they are negative by this method it is signified by a *minus* sign in brackets (-).

A dose of from 1 to 3 c.cm. of carbon tetrachloride was given to each student at 6.40 a.m., before any food had been taken. The drug was given with a small quantity of water. There was no frowning or other evidences that the children objected to the drug, and an hour afterwards they took their regular morning meal. One twelve-years-old boy vomited when he had finished his meal, but the manager informed us that this child often vomited. Each child was furnished with a "chatty," on which was a number corresponding to a number on a tag tied securely to the child's wrist. A dispenser was present during the time this experiment was being carried out, and when a child wanted to use its "chatty" the dispenser compared the numbers, so as to prevent mistakes in the use of the vessels. The manageress assisted with the girls in the same manner. Two children failed to go to stool on the day the treatment was taken; the others had from one to seven stools each, with an average number for the sixty-four children of 2.93 stools; which indicates that the drug is a mild aperient. A dose of magnesium sulphate was given on the second morning after treatment to save time in collecting the stools. This purgative was taken before the early morning meal and all the stools passed that day were saved.

Four hundred and six stools were collected during the two days, which is an average of 6.34 stools from each patient. Each day a small quantity of formalin was poured into these vessels to preserve the stools. These were taken to the laboratory, where each collection of faeces was washed thoroughly on a sieve of fine wire gauze (forty strands to the inch); all that would not pass through the mesh was washed out on to a large flat-plate photographic dish and searched for worms. It was washed again and placed in small quantities at a time in Petri dishes, and examined first upon a white and then upon a black background, because hookworms are dark when they are engorged with blood and preserved in formalin, and show up well upon a white plate, whereas those that contain no blood are discovered more easily on a black background.

A total of 2,776 hookworms, or an average of 43.3, were recovered from the 64 collections of stools. But of these 5 were negative. Besides these, 260 ascarids were obtained from 32; 15 trichuris from 6; and 4,945 *Oxyuris vermicularis* from 58 students. The discharge of trichuris and oxyuris indicates that the drug acts throughout the intestinal tract, for we have not previously seen trichuris expelled after the use of other anthelmintic drugs, or *Oxyuris vermicularis* passed in such large numbers.

Ten days after the treatment samples of the stools of 54 of the students were examined for ova (unfortunately samples of the other 10 were not available as the students had gone away on vacation); 2 of these were positive for hookworms by the simple smear method, and 4 were positive by the combined centrifuge and salt flotation method, which is a percentage of 88 probable cures.

The drug was given to a number of young children who had previously been treated with chenopodium on one or more occasions; the amount of chenopodium which was given

to children of 4 years of age was 4 minims divided into two doses and taken early in the morning with an hour's interval between each dose. This is as much as may be administered safely to children of this age. Table II shows the result—namely, that carbon tetrachloride will remove all or a large number of hookworms which remain after treatment with chenopodium.

TABLE II.

No.	Age.	Sex.	Previous Treatment with Chenopodium.	Dose of Carb. Tetrachloride.	Worms Expelled.			Examination of Faeces after Treatment.		
					Hookworms.	Ascaris.	Trichuris.	Hookworms.	Ascaris.	Trichuris.
1	4	M.	Once, 10 days previously	10 minims	9	1	0	-	+	+

3	3	F.	Twice, 15 and 32 days previously	10 "	35	1	0	-	+	+
4	6	M.	Twice, 23 and 34 days previously	10 "	52	3	1	(+)*	+	+

(+)* = Centrifuge and salt flotation method positive for ova.

The drug was given to a number of children who had pyrexia from various causes, and were anaemic and emaciated; larger doses were used than with the children shown in Table II; the results were excellent and are shown for a few of the cases in Table III. None of the children were in any way inconvenienced by the drug.

TABLE III.

No.	Age.	Sex.	Disease.	Dose of Carb. Tetrachloride.	Temperature at Time of Treatment.	Worms Expelled.			Examination of Faeces after Treatment.		
						Hookworms.	Ascaris.	Trichuris.	Hookworms.	Ascaris.	Trichuris.

Conclusions.

1. Carbon tetrachloride is an efficient anthelmintic remedy for hookworms.
2. The drug may be administered safely in doses of 10 to 20 minims to children of 3 and 4 years of age, even when they are seriously ill from various causes.
3. It aids the expulsion of *Ascaris lumbricoides* if it is followed by a purgative, but it is not as effective as chenopodium in killing this worm.
4. The drug does not seriously deteriorate on keeping. Many children were given doses of carbon tetrachloride which had been stored in the laboratory for three years.
5. It is more valuable than chenopodium for campaigns against hookworm disease because—

- (a) Patients do not object to its taste.
- (b) It is not necessary to precede or follow the administration of it by a purge.
- (c) It is more efficient than chenopodium and has not the depressing effects of that drug.
- (d) It is much cheaper than any other drug that has been used.
- (e) It can be prepared in a high degree of purity, and a chemically pure preparation should always be used.
- (f) The person who is being treated can do his usual day's work.

Children when one year of age may be given 10 minims of carbon tetrachloride with safety, and this dose should be increased by 2 minims for each year of apparent age. Thus a child of ten would receive 28 minims, a youth of sixteen

40 minims ($2\frac{1}{2}$ c.cm.), and an adult dose should be from 50 to 80 minims (3 to 5 c.cm.), according to the size of the patient.

Finally, elonopodium is soluble in carbon tetrachloride, and a mixture of one part of the former in four of the latter should prove to be efficient for the expulsion of *Ascaris lumbricoides*.

Our thanks are due to Dr. W. P. Jacobs of the Rockefeller Foundation and Dr. Cathorino Anderson of the Lady Havelock Hospital for much kindly assistance.

SOME OBSERVATIONS ON THE MECHANISM OF DRUG ACTION:

A STUDY IN PHARMACO-DYNAMICS.

BY
O. C. M. DAVIS, M.D., D.Sc.,

LECTURER IN MATERIA MEDICA IN THE UNIVERSITY OF BRISTOL;
PHYSICIAN TO OUT-PATIENTS, BRISTOL ROYAL HOSPITAL
FOR SICK CHILDREN AND WOMEN.

It has long been recognized that certain chemical compounds have very little effect upon the animal organism, whereas others produce a marked reaction when administered under similar conditions. The object of the present paper is to bring together some scattered observations which help to throw some light on such facts as these, and to explain the mechanism of pharmacological action. The subject will be dealt with under several headings, and the first one is naturally a consideration of the question of

Toxic Properties in Relation to Atomic Weights.

About the year 1815 Prout, who was a physician, published a paper in the *Annals of Philosophy* pointing out that in many cases the atomic weights of the elements were approximately whole numbers, and deducing from this that hydrogen was the primary matter from which all elements are formed by various condensations. The observations of Prout and the work of Newlands, Lothar Meyer, Mondelejeff, and others led to the well-known periodic classification of the elements.

This classification led to much valuable research and to many important discoveries, but apparently little has been written from the point of view of pharmacological relationships. A careful consideration of the periodic table reveals the fact that there are many relationships between the pharmacological reactivities of the elements (and their compounds) and their periodic grouping. A few examples will illustrate this point; if we compare the elements of the magnesium group we notice that the tendency is towards increase of toxicity with increasing atomic weight, the greatest toxicity being associated with mercury compounds. The oxygen group is also of interest, passing from a gaseous element to a typical solid non-metal, sulphur, thence to selenium and tellurium, with certain metallic characteristics. The hydrogen compounds of this series illustrate well the increase of toxicity with increase of molecular magnitude, starting with the innocuous substance water, and passing to the extremely toxic telluretted hydrogen.

A very valuable research was carried out by Michel¹ in 1881 on the relative toxicities of a number of metals. He experimented upon fishes with solutions of metallic chlorides, diluting the solutions so that the fishes could survive forty-eight hours in the diluted solutions. He applied the term "limit of toxicity" to the weight of metal present in the form of chloride which would be contained in 1 litre of such a solution. In his original paper he deplores the fact that no relationships between toxicity and atomic weight were observed. Unfortunately this is a case where an excellent research was largely thrown away from a scientific point of view by misinterpretation of the actual findings. Had he tabulated his results in weights proportional to atomic weights many relationships would have been revealed, but he was presumably ignorant of the nature of "molecular solutions." One example shows this fairly well.

	Michel's Values.	Michel's Values Recalculated and Multiplied to give whole Numbers.	Atomic Weight.
Calcium	2.4	600	40.0
Strontium	2.2	250	87.6
Barium	0.78	56	137.4

It is clear from this table that the toxicity of an element belonging to the same periodic family increases with increase in atomic weight, but, needless to say, such a law is subject to variations. It is highly improbable that such periodic relationships as have been referred to are accidental, and with increasing knowledge more light may be thrown on this interesting branch of pharmacology.

Influence of Solubility.

One of the factors long recognized as influencing pharmacological activity is the solubility of the drug concerned. There are so many well-known examples of this that it is quite unnecessary to refer to them in detail; it is sufficient to point out that in practical pharmaceutical chemistry various methods are used to increase the solubility of insoluble compounds; thus slightly soluble alkaloids are converted into more soluble alkaloidal salts, and in the realm of synthetic organic chemistry various groups are introduced into the molecule with the object of increasing solubility.

It has also been recognized that certain constituents of animal organisms exert a selective action in dissolving drugs introduced into the organism, and thus certain tissues are specially affected.²

Vapour Pressure.

Its vapour pressure is a factor of the greatest importance in its effect on the reactivity of the drug. For instance, chloroform, ether, and other volatile anaesthetics would be useless for the purpose if they did not possess a high vapour pressure. During the recent war the question of vapour pressure was of the utmost importance in connexion with gas warfare. It is terrible to think of the calamitous possibilities of easily prepared toxic substances possessing a high vapour pressure.

Relationships between Chemical and Pharmacological Reactivity.

The increased attention given to the synthesis of organic compounds during the middle and later years of last century has enabled chemists to determine the structure of chemical compounds and in collaboration with pharmacologists to demonstrate relationships between the chemical and physiological reactivity of drugs.

Some years ago³ the rates of hydrolysis of a considerable number of anilides were investigated by the writer. These compounds, of which acetanilide (antifebrin) and phenacetin are common examples, owe their activity in part to the fact that they are hydrolysed slowly within the organism with liberation of the parent base according to the general equation—

It was shown that there were definite relationships⁴ between velocity of decomposition and degree of toxicity as previously determined by various pharmacologists.

Chemical Affinity.

In a further research⁵ on isomeric substances having similar pharmacological action, it was shown that in certain cases chemical affinity and toxicity were quantitatively proportional. Such observations have more than a theoretical importance; for example, this difference in chemical affinity doubtless explains the differences observed by Breinl and Nieronstein when carrying out experiments upon trypanosomes with sodium salts of the isomeric amino-phenyl-arsenic acids. These observers found that the para compound, also known as atoxyl, is very reactive, the meta compound less so, and the ortho compound inactive.⁶

The relationship between the compounds is shown by the following formulae:

Another example of varying pharmacological activity is seen in the case of the isomeric hydroxy-benzoic acids, the ortho compound, better known as salicylic acid, being the only one possessing marked reactivity.

"Affinity Constants."⁷

Ortho-hydroxy-benzoic acid	0.102
Meta-hydroxy-benzoic acid	0.00867
Para-hydroxy-benzoic acid	0.00285

Rate of Formation of Excretion Products.

In a paper referred to above⁹ it was pointed out that the toxicity of a drug must partly depend upon the relative velocities of formation of "cell-drug" compounds and excretion products. To take a well-known example, the toxicity of hydrocyanic acid doubtless depends to some extent upon relative slowness of formation of excretion products as compared with the rate of formation of an active "cell-drug" compound.

A case which supports this theory may be referred to here—namely, that of the three isomeric aceto-toluidides whose rate of hydrolysis and pharmacological reactivity have both been investigated. The hydrolysis rates are as follows, "K" being a constant expressing velocity of hydrolysis:

	K.
Aceto-ortho-toluidide	0.709
Aceto-meta-toluidide	3.14
Aceto-para-toluidide	3.11

If the relative toxicity of these compounds depended only upon rate of hydrolysis it is obvious that the ortho compound would be the least toxic. This is not so actually, since the meta and para compounds are both non-toxic, the ortho derivative alone possessing toxic properties. This apparent anomaly may be readily explained by a consideration of certain observed facts. It has been found⁹ that all three of these compounds may be oxidized with potassium permanganate to acetyl-amido-benzoic acids according to the general equation—

Furthermore, it is known that acetyl-meta-amido-benzoic acid appears in the urine of dogs after administration of meta-aceto-toluidide.¹⁰ That is, it is easier for the organism to excrete this compound as a relatively non-toxic product obtained by direct oxidation, rather than by oxidation subsequent to hydrolysis. A series of laboratory experiments have been made by the writer which demonstrate that the rate of oxidation of the ortho compound by potassium permanganate is much slower than that of the meta and para isomers under similar conditions.

It is thus seen that the only toxic isomer is the one which is least readily oxidized; in other words, a physiological reaction is produced at a greater rate than an excretion product of diminished toxicity can be formed.

Unsaturated Valencies.

The question whether or not the carbon atoms, and sometimes other atoms, in a chemical compound are saturated or unsaturated may have an important bearing on the pharmacological action of the compound. It has been recognized as a general rule that open chain derivatives containing unsaturated carbon atoms are more toxic than isomeric saturated bodies; thus allyl alcohol is fifty times more toxic than normal propyl alcohol.

Thiele¹¹ holds that in unsaturated compounds the combining energy of every atom which participates in the double linking is not completely absorbed, so that the atoms still possess valency (partial valenz), and it is in this partial valency that the source of reactivity is to be found.

Some light is thrown on the phenomenon of increased toxicity of unsaturated substances by comparing the properties of certain oxygen and sulphur compounds. It has been shown by Peters¹² that the replacement of oxygen by sulphur may increase "the residual affinity" of a compound. Thus one gram-molecule of silver cyanate absorbs one gram-molecule of ammonia, whereas one gram-molecule of silver thiocyanate absorbs two gram-molecules of ammonia under similar conditions. In a recent paper¹³ on the influence of sulphur as a colour-producing element numerous examples are given in which the replacement of oxygen by sulphur produces coloured compounds from colourless ones, and it is shown that the heats of formation of the sulphur compounds are less than those of the corresponding oxy-compounds, supporting the suggestion that the substitution of sulphur for oxygen gives rise to less stable compounds, and that the chromogenetic properties of sulphur depend upon the formation of compounds possessing residual affinity. These observations are very significant when it is remembered that, the replacement of oxygen by sulphur in chemical compounds

frequently increases their toxicity; thus paraldehyde is a safe hypnotic with no action upon the heart, but tri-thioaldehyde is a powerful heart poison. Carbon disulphide is also more toxic than carbon dioxide, and sulphuretted hydrogen, unlike its oxygen analogue water, is a very toxic substance.

Adsorption Phenomena.

The subject of adsorption has been dealt with by numerous workers, and has given rise to a large amount of literature; many theories have been advanced to explain the phenomenon, and it has been shown¹⁴ that adsorption may consist not only of a surface action, but that this may be accompanied by diffusion inwards of material deposited on a surface. Some of the experiments referred to above extended over a period of eleven years, and were finally completed by Professor J. W. McBain.¹⁵ These and other experiments have led to the belief that adsorption may play an important part in pharmacological action and pathological processes. Moore and Roaf,¹⁶ who made laboratory experiments with anaesthetics upon brain tissue, etc., concluded "that anaesthetics form unstable compounds or aggregates with the proteins of the tissue cells, and that anaesthesia is due to a paralysis of the chemical activities of the protoplasm as a result of the formation of such aggregates."

In a recent paper¹⁷ it is suggested that certain pathological states are initiated by the adsorption of toxins on the surface of specialized cells, and that if these surface layers be not removed permanent damage to the tissues may be brought about by the inward diffusion of these superficial layers. In this connexion it must be remembered that an extremely thin layer of adsorbed material may alter all the properties of the solid so covered,¹⁸ and experience in the field of chemical reaction known as catalysis has demonstrated that adsorption layers are the seat of enormously enhanced chemical reactivity.

Idiosyncrasy.

Such an article as this would be incomplete without brief reference to the undoubted fact that some people exhibit a marked intolerance towards certain drugs, and conversely other individuals may be able to tolerate abnormally large doses of some special drug, and this must be borne in mind when attempts are made to compare the relative potencies of a series of chemicals. The writer was for a considerable period associated with a scientist who was able to inhale concentrations of noxious gases at least twice the magnitude that a normal man could bear, but after two years' work at such research his resistance in this respect broke down, and his sensitivity to gases became normal. It is not possible to explain such idiosyncrasies as this, but they are certainly of great clinical importance.

In conclusion, it is to be hoped that with increasing knowledge of the constitution of chemical compounds, combined with increased activity of experimental pharmacologists, in the near future the sciences of chemistry and pharmacology will be more intimately associated, to the mutual advantage of both scientists and clinicians.

HEALTH conditions in the Ukraine remain disquieting, according to a report received from the Health Section of the League of Nations. Contrary to former experience at this time of the year, a very pronounced upward tendency of the typhus wave, with a heavy mortality rate, is reported. Cholera is also increasing. The needs of the moment are more than ever in excess of the resources of the Ukraine health administration, which is being forced to close one hospital after another.

VISCERAL CRISES.

BY

ARTHUR MILLS, M.D.,

DUNDEE.

LOCOMOTOR ATAXIA, with its well-defined and uniform group of symptoms, has been familiar to us for a period of about seventy years. That locomotor ataxia is syphilis pure and simple is only now becoming a universally accepted fact, and it does not seem unreasonable that its clinical symptoms might be reconsidered—first in the light of our now certain knowledge as to its etiology, and secondly in the light of our increasing knowledge of the varied manifestations of inherited and late syphilis.

Not infrequently there is evidence that the morbid process in tabes is widely distributed. Atrophy of the optic nerve is common; atrophy of other cerebral nerves is frequently noted. There are instances in which tabes is associated with general paralysis, the cerebral cortex becoming involved, and quite frequently symptoms may be present the result of lesions in motor nerves and nuclei and of degeneration in peripheral nerves. We do not, however, look upon such symptoms as diagnostic of tabes. If, amid these various symptoms indicative of a widespread syphilitic involvement of the nervous system, we are unable to recognize others the result of an accidental selection of the posterior nerve root system, we are not warranted in making a diagnosis of tabes. The destructive process in this posterior root system leads to symptoms due to interference with and cutting off of afferent impulses from various parts of the nervous system, and these alone form the classical symptoms of tabes. Ataxia, hypotonia, Westphal's phenomenon, and sensory disturbances are usually interpreted as being due to impairment of function; hyperaesthesias, paraesthesias, and girdle pains present the character of irritative symptoms. The purpose of this paper is to point out that visceral crises should not necessarily be included in the last-mentioned group of posterior root irritative phenomena, but should be looked upon as evidence of the morbid process being probably present elsewhere. In particular it is desired to demonstrate that they are not peculiar to the condition of tabes.

Visceral crises are paroxysmal in character. There is a sudden disturbance in function usually with pain, lasting a variable time, hours or days, and terminating as a rule abruptly. Recurrence is a marked feature of these attacks, and no sufficient external cause for the attack can be found. They have frequently been mistaken for acute surgical conditions. So far as I can learn, the visceral symptoms of tabes have never been satisfactorily explained by reference to their anatomical basis, and yet there is a persistent tendency to group them with root pains and to regard them as of radicular irritative origin and of diagnostic importance.

Of all the classical symptoms of tabes, root pains, however, form probably the symptom which is most constantly met with. In a series of about 450 referred to by Starr,¹ 98 per cent. of these patients suffered from pains and only 10 per cent. from gastric crises. There appears to be as yet no generally accepted theory as to the mechanism of the production of these symptoms. Charcot originally attributed gastric crises to disease of the sympathetic, and many others adopted the same view. Dr. T. Buzzard suggested that they are due to a lesion in the vagal nucleus. Peripheral neuritis has also been offered as an explanation; Barker,² describing a case in detail and endeavouring to make a theory to fit the pathology, suggested irritation of dorsal root fibres causing a reflex vaso-constriction in the splanchnic area.

Purves Stewart³ considers that the various visceral crises of tabes may be due to irritative changes in various parts of the autonomic nervous system. There is no reason that I am aware of to regard pathological irritative changes in various parts of the autonomic system as peculiar to tabes; in fact it is difficult to refer such changes to spinal or posterior root degenerations. They have little apparent connexion with these, and yet the same author, when discussing abdominal pain and the differential diagnosis between visceral crises and acute abdominal disease, looks to the finding of the classical symptoms of tabes to save us from error. This indeed is the usually advocated procedure in textbooks of medicine and surgery. If in doubt as to whether the condition is a visceral crisis or not, we are asked to investigate the knee-jerks and ankle-jerks and to look for symptoms of ataxia and sensory disturbances characteristic of disease of the posterior columns and roots.

Etienne,⁴ discussing the frequency of aortitis in syphilis, quotes a case where the pain was situated in the epigastrio region and recurred in violent gastric crises as in tabes. The autopsy showed a suprasigmoid aortitis with stenosis of the coronary arteries. He admits that clinical symptoms in such cases are sometimes absent, but concludes that the aortitis was the cause of the crises in the case mentioned. Pathant,⁵ in a communication entitled "Sur la fréquence des accidents gastro-intestinaux d'apparenco banale qui doivent être imputés à la syphilis," describes a case where the patient suffered from painful attacks of colic and vomiting presenting all the characters of a gastric crisis of tabes. The patient had no other symptoms of tabes and made a rapid recovery with antisyphilitic treatment. He states further that had the diagnosis of syphilis not been made the patient would very probably have been subjected to a fruitless operation. This author is content in this instance with a diagnosis of gastric syphilis. Both these writers emphasize the similarity of their patients' symptoms to the gastric crises of tabes, but do not suggest that they may be of an identical nature.

Our advancing knowledge of the pathology of late syphilis may soon throw light upon this problem, and will probably show that these crises are due to a syphilitic infection of the autonomic nervous system. As described by Warthin,⁷ this new pathology is based upon the demonstration that the essential tissue lesion of either late or late-acute syphilis is a mild irritative or inflammatory process due to the localization in the tissues of relatively avirulent spirochaetes, and that inflammations of this type may occur in all tissues and organs. We have to understand that the gumma is a comparatively rare lesion in old syphilis and that the pathological diagnosis of syphilis is microscopic and rarely to be recognized by the naked eye. Such a pathology opens up for us a limitless field for clinical manifestations, and only the universal application of the Wassermann or other reliable test, along with careful clinical observation, especially as regards the results of treatment, will enable us to come to some understanding of the vast symptomatology of this disease. Patients attending venereal disease centres and suffering from acute and manifest syphilis, chancres, secondary manifestations, and gummata, appear to be outside of this problem entirely, and we cannot therefore look for much assistance from these clinics. We have to find out what symptoms may be caused by inherited "latent" and late syphilis. The task appears to be one peculiarly associated with general practice.

Observation and consideration of the following cases suggest that syphilis may be the cause of the visceral crises hitherto associated with tabes, and that these attacks are not peculiar to the special pathology of tabes.

CASE I.

Female, aged 29, unmarried. She first came under my observation in March, 1919, her complaint being recurrent attacks of abdominal pain and sickness. Her first attack had occurred in the summer of 1916, when she was seized very suddenly with severe pain in the abdomen and with vomiting. Since then she had suffered from these attacks at very frequent intervals; usually they lasted under twelve hours. The pain would come on suddenly early in the morning, and by late afternoon or evening both pain and sickness would cease quite abruptly, and she would be ready to go about as usual. The pain occasionally lasted two days or more, and she was off work one day, back to work the next, and then possibly off the following day with another attack; she rarely had more than a week or two at a time of freedom from these seizures. She had consulted several doctors, and appendicular colic had been suggested. In October, 1920, she had a more severe and more prolonged attack than usual and was now very anxious to have something done. I could feel a freely movable right kidney and was inclined to attribute her attack to this, but fortunately I asked Mr. D. M. Greig to see her with me in consultation. He suggested a Wassermann test, and the report was definitely positive; her family history also indicated inherited syphilis. She received three injections of 0.6 gram neo-kharsivan at weekly intervals and was given mercury to take by the mouth. She has had no further attacks, and has been well for over a year. I have no doubt whatever that the case is one of inherited syphilis, and that her attacks were due to syphilis. She has had none of the classical symptoms of tabes.

CASE II.

Female, aged 27, unmarried. This patient was seen by me for the first time in June, 1919. Her troubles dated from childhood, the chief one being that she suffered from frequent attacks of pain in the abdomen, sometimes, but not always, associated with vomiting; between these attacks her stomach gave her no trouble. In March, 1917, an attack of abdominal pain more severe than usual led to an emergency laparotomy being done. The surgeon who operated and removed the appendix was able to show me his notes of the case. He found no surgical abdominal condition, and the pathologist's report on the appendix was negative. She continued to suffer from these attacks. Her family history was

suggestive of syphilis, and the Wassermann report on her serum was definitely positive. She had no symptoms of tabes. Mercurial inunctions and mercury by the mouth were soon followed by marked improvement, and on January 12th of this year she reported that she had had no attacks for six months or more. It should also be noted that a brother of this patient was submitted to an appendicectomy at the age of 16, and that his appendix was also found to be normal; no surgical condition was found in the abdomen. He died on the third day after his operation. The cause of his death was believed to be delayed chloroform poisoning.

CASE III.

Male, aged 49, married. I was called to see him on January 31st, 1921, when he was suffering from pain in the epigastric region and vomiting; he had never suffered from this before, and no cause whatever could be discovered for his illness. His pain and vomiting lasted for a week. He had no rise of temperature, but his tongue in time became furred and his pulse increased a little in frequency; his bowels moved normally. Pain was the outstanding feature; he became very impatient as regards the pain, and a surgeon's opinion was suggested but not insisted upon, for I could not convince myself that the condition was a surgical one. I could, however, make no diagnosis satisfactory to myself. The attack subsided, but left him very weak; he had had no nourishment and very little sleep for a week, for I had withheld morphine in the expectation of making a definite diagnosis. I received an urgent call to see him again on the afternoon of March 25th. Returning to his work after his usual midday meal, he had been seized with sudden severe pain in the epigastrium and violent vomiting, and had been carried home in a collapsed condition. He had crawled upstairs and lain on his bedroom floor in agony unable to get into bed. I saw him about 4 p.m., by which time the pain and vomiting had ceased. He was off work only two days. He informed me that he had had a similar attack, not so severe, at the end of February, and had then only been one day off work. Between these attacks he had had no complaints. I could get no definite history of syphilis, but he admitted having run the risk of infection in his youth. The Wassermann report was definitely positive; his wife's blood was also definitely positive, and I discovered she was suffering from a gumma. She had had three miscarriages and then one very delicate child, born twelve years after marriage. I failed to find, and still fail to find, any of the classical symptoms of tabes in this patient. He has had mercury by the mouth, from 6 to 12 grains daily, since April 1st. An attempt to use mercurial inunctions was followed by a severe dermatitis. Examined on January 18th of this year he was well, and had had no further attacks of abdominal pain.

Had these patients shown the classical symptoms of tabes, the attacks from which they suffered would have been diagnosed as gastric crises. They were the subjects of inherited and late syphilis. Their attacks yielded to antisyphilitic treatment, and quite frequently in the treatment of locomotor ataxia by vigorous antisyphilitic methods improvement is reported as regards the visceral crises, though there may be none as regards the ataxic symptoms. Visceral crises are relatively uncommon in locomotor ataxia, being observed in only about 10 per cent. of those cases. Syphilitic visceral crises such as I have described may be relatively frequent and may account for many vague conditions and many errors in diagnosis and fruitless laparotomies. In particular I shall look with grave suspicion upon every case diagnosed as "colic," "appendicular colic," "kinks," "bands" and "adhesions," "cholelithiasis without gall stones," and so forth. The investigation of the knee-jerks will not save us from error, but the application of the Wassermann test may do so. My conclusion is that visceral crises are a manifestation of inherited and late syphilis, and are not peculiar to tabes.

In Moseley's classification of the elements founded on x-ray spectra there were four vacant places of ordinal numbers—43, 61, 72, 75. Moseley himself suggested that the number 72 probably belonged to the element cerium previously described by Professor Urbain of Paris. In June, 1914, Professor Urbain, with the late Sir William Ramsay, went to Oxford in order to investigate these and other related matters along with Moseley. The results with regard to cerium were inconclusive, but Moseley was to have published a paper on the inquiry. He joined the army at the beginning of the war, and his death at Gallipoli was an irreparable loss to science. Professor Sir Ernest Rutherford, whose pupil Moseley was, has now written to *Nature* to accept Professor Urbain's identification of cerium with the element having the number 72. Proof has been given in a paper communicated to the Académie des Sciences by M. Dauvillier.

MEDICAL, SURGICAL, OBSTETRICAL.

QUININE NECROSIS OF MUSCLE.

The interest of the following case relates to the early treatment of the patient by intramuscular injections of quinine and its unusual sequel. Necrosis took place, but in none of the other cases of quinine necrosis recorded has there been as in this case, a definite separation and encysting of the necrosed muscle. The specimen is now in the museum of the Royal College of Surgeons of England.

J. S., an ex-soldier, contracted malaria in Salonica in October 1916. Rings and crescents are said to have been found in his blood at various times. He was invalided to the United Kingdom in February, 1917, and had relapses about once a month till he came under specialist treatment, when the relapses gradually decreased in frequency, the last being in February, 1921. In 1916 he had about forty-nine injections of quinine into each buttock alternately every other day, but we are unable to discover the particular form of quinine used. About a month after the course of injection had ended he noticed a swelling in the right buttock "first feeling like a lot of little lumps," but shortly he noticed "one big lump," as was the condition when he first came under the notice of one of us (P. F.).

On examination, there was a cigar-shaped swelling some three inches long in the upper part of the right buttock, the skin moved freely over it, and the lump itself appeared to be movable on the deep structures. It was somewhat tender to the touch, and owing to its position frequently received slight blows and caused much discomfort and even pain. It was therefore decided to remove it.

Operation took place on February 7th, 1922 (D. P.). An incision was made over the whole length of the swelling, and on cutting through the skin and superficial fascia the tumour was found to be lying in, and parallel with, the upper part of the gluteus muscle. Cutting into it, an adventurous bursal sac was opened in which a greyish white cigar-shaped body lay quite free. This was removed. It was quite smooth, firm in consistence, somewhat elastic, and had a smooth glistening surface, similar to the space in which it lay. The adventitious sac was cut away from the surrounding muscle, and the space left closed with catgut; the fascia was sutured with catgut and the skin with silk-worm gut.

The tumour measured 3½ inches by ¾ inch by ½ inch. A longitudinal incision into it showed that it consisted of wavy bundles of fibrous-looking material, dry and bloodless, and there was some slight calcification at one part near the centre. A section was cut by Dr. H. H. Sanguinetti, and it was seen that the greater part of the tumour consisted of necrosed muscle fibre, much of it still lying to the injection of the drug and also to the direct action of the drug and also to pressure of the injected fluid in the muscle bundle proving so great that the blood supply to the bundle was cut off. The dead part of the muscle must have remained sterile, a line of demarcation was formed round, it separated from the surrounding tissue but was not absorbed, and so acted as a foreign body and became encapsuled.

THE BLOOD AT 100 YEARS OF AGE.

While carrying on a research on pallor, the case of a lady aged 100 was encountered. As few people reach this age, and as records of their blood are seldom obtained, blood counts were done on two occasions. The following are the particulars:

	Feb. 9, 1922.	Mar. 2, 1922.
Red blood corpuscles ...	4,600,000	4,350,000
Hæmoglobin ...	81 %	78 %
Colour index ...	0.88	0.90
White blood corpuscles ...	7,150	7,200
Differential count:		
Polymorphonuclear leucocytes ...	42.5 %	51.0 %
Eosinophil leucocytes ...	4.0 %	4.0 %
Basophil leucocytes ...	0.2 %	0.5 %
Small lymphocytes ...	43.0 %	37.0 %
Large lymphocytes ...	7.3 %	6.0 %
Large hyaline mononuclear ...	3.0 %	1.5 %

Remarks.

The red blood corpuscles are well formed and of normal appearance. One normoblast was observed on February 9th. The white blood corpuscles show a relative lymphocytosis in comparison with the blood of an average healthy adult and there are more eosinophil leucocytes than usually found. Except for an old ununited fracture of the neck of the femur

which limits her activity the patient enjoys good health and her mental faculties and memory are in no way impaired. Her age is fully authenticated.

TREATMENT OF ERYSIPELAS BY VACCINES.

A STATEMENT appeared recently in the *BRITISH MEDICAL JOURNAL* to the effect that antistreptococcal vaccine was of doubtful value in erysipelas. It might be of interest, therefore, to record a typical case of facial erysipelas treated successfully by antistreptococcal vaccine.

The patient was a young woman, aged 29, who was taken suddenly ill with rigors and a raised patch of erysipelas on the side of the nose. This rapidly spread over the forehead, and the patient's temperature rose to between 104° and 105°. Iodol was tried locally, but failed to stay the spread of the disease to the scalp. I obtained the help of a trained nurse, and procured a supply of antistreptococcal vaccine. At 9.15 a.m. on March 18th, 1922, I injected a dose of five million, with the result that in less than twenty-four hours the temperature fell from 104° to 99.2°. A second dose of twenty million was then injected, and the

temperature fell to normal, remaining subnormal for several days. The patient made an uninterrupted recovery.

This was the first case of erysipelas in which I have tried antistreptococcal vaccine (supplied in this case by Messrs. Parke, Davis and Co.), and I was much struck by the immediate improvement in the local and general condition of the patient.

Reports of Societies.

AN ORGANISM FROM CANCEROUS GROWTHS.

At a meeting of the Edinburgh Obstetrical Society held on June 14th, with the President, Dr. LAMOND LACKIE, in the chair, Dr. JAMES YOUNG read a paper on a further study of an organism obtained from cancerous growths. He had stated in previous papers that a similar organism was obtained from human and mouse cancer, and from three cases of leukaemia in the human subject. It grew in one phase as a small bacillus or as a long filament, and had been identified as belonging to the coli-typhoid group. He had found that the mouse strain when injected into mice produced a diffuse lymphomatous or lympho-sarcomatous lesion.

In the present paper he gave an account of the life-cycle as studied in the experimentally produced mouse lesions. In an animal killed while suffering from the early lesions the organism was found enlarging into forms suggestive of a blastomycete, and little colonies could often be seen in the tissues showing all the stages in the evolution. In animals killed when suffering from the chronic lesions, on the other hand, the smaller phases were usually absent, and the blastomycete phase alone was found—often only after a diligent hunt—as round or oval bodies that were usually structureless. Sometimes, when stained with a Romanowsky stain, they exhibited purple granules. When fully developed the body itself stained blue. Dr. Young had from an early stage been studying these bodies in cancerous tissues, and in previous communications had stated his belief that when the tumour tissue was incubated in a suitable fluid medium they could be seen to germinate into minute cocci, bacilli, or filaments, the actual mode of germination differing in different cases. He showed illustrations exhibiting the different forms of this germination process, as studied in human and mouse cancer and in the chronic lesions of experimentally infected mice. Dr. Young stated that, alike on experimental and morphological grounds, the investigations provided a strong body of evidence in favour of the etiological relationship of the organism to malignant disease. He then showed how the bacteriological investigation of his results as carried out in the Bacteriological Department of the Royal College of Physicians Laboratory, Edinburgh, had brought this aspect into direct conflict with bacteriological teaching. The organism which

he used for his injection experiments, and which was obtained from mouse cancer, was identified by its sugar reactions as a *B. coli communis*. With this in a carefully controlled series of experiments he had obtained all the chronic lesions, and he felt justified in concluding that the results were directly related to the experiments. On the other hand, from only a few of the lesions had a lactose fermenter been recovered. In the majority of the cases examined a non-lactose fermenter had been obtained belonging to the paratyphoid B, Gaertner, and Aertrycke group. It was well known that an organism (or organisms) of this group were responsible for a common and acute epidemic in laboratory mice. The organism recovered from the chronic lesions when exhibited to mice produced death after periods varying from fourteen hours to eight days. In the animals, except those that died with very acute manifestations, a diffuse lymphoid lesion accompanied by active cellular proliferation was produced, varying only in its degree and in some other respects—that is, the signs of toxæmia—from the chronic lesions produced after injection of the lactose fermenter. Dr. Young said that he was unable to offer an opinion on this purely bacteriological aspect of the research. He felt, however, that it could not be without significance that he had found the blastomycete forms in the tissues of animals infected with the non-lactose fermenter.

Professor RUSSELL said that he had never wavered from the belief that cancer was due to a parasite and he was specially interested to find that Dr. Young was describing blastomycete-like forms in his research. It was now thirty-two years since he first drew attention to the existence of blastomycetes in cancerous tissues.

Dr. YOUNG, in reply, expressed his belief that Professor Russell's early observations would be proved to be correct.

Dr. H. S. DAVIDSON and Dr. DOUGLAS MILLER read a paper on a "Record of eclampsia in the Edinburgh Royal Maternity Hospital during the years 1912-1921."

Reviews.

THE CAUSATION OF FOETAL DEATH.

THE Ministry of Health has issued a report by Dr. EARDLEY HOLLAND on the causation of foetal death, with an introduction by Sir GEORGE NEWMAN. It contains a special section on the "recognition of congenital syphilitic inflammation of the long bones" by Professor Hubert Turnbull, D.M.

The report is described as an investigation into the factors which determined death in a sample of three hundred foetuses of viable age. The specimens were obtained from fifteen of the metropolitan hospitals; the City of London Maternity Hospital supplied more than a third of the cases (102), and the London Hospital 69, or nearly a quarter. There were 122 other foetuses over and above the 300, but they were not used for the purposes of the investigation chiefly because they were not of viable age. The work was begun in 1914 by Dr. Holland and the late Dr. P. B. Ridge, and a great deal of the working up of the material had been accomplished before 1917, when Dr. Holland went to France in the R.A.M.C. The actual investigation, therefore, is considerably older than the date (1922) which stands on the title-page; indeed, the schedules of the order of examination of the mother, the foetus, the placenta, and the father which were drawn up by Dr. Holland have been used by other investigators, and results obtained from them have already been published.

Dr. Holland took great pains to get exact clinical and obstetrical details in all cases; they were entered on two printed blanks headed "The Mother" and "The Father" respectively; but it had to be confessed that the latter was "a most elusive person," and that not much was elicited regarding him. The results of the pathological examination of the foetus and placenta were recorded on two other blanks, special attention being paid to the search for the spirochaetes of syphilis. The research, therefore, is of high value in relation to the incidence of this disease as a factor in the production of stillbirth; it is interesting to note that the frequency given is much the same as that obtained by other workers.

The author is concerned with the definition of terms and

¹ Reports on Public Health and Medical Subjects. No. 7. Ministry of Health. The Causation of Foetal Death. By Eardley Holland, M.D., F.R.C.S., F.R.C.P., Surgeon to the City of London Maternity Hospital, Assistant Obstetrical Physician at the London Hospital. London: Published under the authority of His Majesty's Stationery Office. 1922. (Pp. 167, with 24 plates, 3 coloured. 1s. net.)

would like to do away with the words "stillbirth" and "deadbirth" altogether. The end of foetal life, he thinks, is not reached until pulmonary respiration has begun; therefore, foetal death may occur not only before and during labour (ante-natal and intra-natal), but also after labour (post-natal), before the lungs have begun to act. Two definitions are given of viability: a foetal length from crown of head to heel of not less than 35 cm., and an age of not less than 28 weeks from the mother's last menstrual period. Some such changes in terminology and definition are desirable, and would help to clarify thinking on a rather difficult subject.

The classification of the causes of foetal death is no easy matter, for to reach a really satisfactory one would postulate a knowledge which is not yet possessed by any investigator. Death may occur at three periods—before, during, or immediately after birth (ante-natal, intra-natal, and post-natal)—and to some extent the causes are peculiar to each of the three; but Dr. Holland takes the "gross clinical condition," when there is one, as the "primary cause," and in its absence the pathological state of the foetus or placenta. Thus placenta praevia is a primary cause, and so is retroplacental haematoma; indeed, there may be four groups of primary causes—namely, maternal states, complications of labour, placental states, and foetal states. The primary cause may not, however, be the actually lethal cause, which may be found in one or other of the subsequent events or "consequent factors" as Holland terms them. Thus, whilst placenta praevia is reckoned as the primary cause, the consequent factor may be foetal anaerobiosis from separation of the placenta or from prolapse of the cord, or foetal haemorrhage from ruptured placental umbilical branches, or cranial injury and cerebral haemorrhage due to the method of delivery. Similarly eclampsia may be the primary cause, with toxæmia of the foetus, retroplacental haematoma, and birth injuries as consequent factors.

More than one consequent factor may be at work in any given case. It is in connexion with one of the consequent factors that Dr. Holland's research opens up new ground, and introduces the little understood condition of intracranial stress and resulting injury to the tentorium cerebelli during the progress of the foetal head through the maternal canals. The idea is attractive, almost fascinating, and it has perhaps charmed Dr. Holland to some extent. He found tentorial tears in 81 cases, with resulting subdural cerebral haemorrhage in nearly all. If it should be discovered that tentorial lacerations, associated with cerebral haemorrhage, occur with anything like the same frequency in the stillbirths of other obstetric centres this cause of death will at once assume immense importance. It will also bring a hopeful note into the preventive treatment of foetal death, at any rate in its intra-natal phase. But even if the association do not prove so common or so fatal as Dr. Holland thinks, he will have done a very useful service in focusing research upon the neglected subject of cranial stress in labour and upon the possible functions of the intracranial septa. The frequency of tentorial tears in breech deliveries is a fact of profound significance, and may revolutionize the management of these presentations.

Another extraordinarily interesting section of the report is that in which foetal syphilis is dealt with. It occurred certainly in 14 and possibly in 16 per cent. of the foetuses examined by Dr. Holland. Among 62 foetuses there were 37 spirochaete-positive and 25 spirochaete-negative; amongst the latter were at least 5 which were undoubtedly syphilitic, whilst the remainder were either probably or possibly so. This important question of the diagnosis of the absence of spirochaetes, and both Dr. Herbert Turnbull (who deals with the bone changes) add many facts to the previous existing knowledge on the matter.

Every part of the report, however, has its own value. Even the suggestion that unusual smallness of the placenta may be a cause of foetal death is thought-provoking, although the known fact that a live infant may be born along with a placenta very largely degenerated and out of commission will cause some hesitation in coming to a decision. The weight ratios of the placenta form another valuable section, and the elaborate tables contain a mine of information on which others will find it profitable to work. There is an addendum containing a list of cases with the cause of death undetermined; on looking over the details one is depressed to find again and again the note (which is also the explanation) "placenta not examined," and one is tempted to ask when those who send foetuses for examination will recollect

that without their respective placentas they are incomplete specimens. A word of praise is due to the illustrations of intracranial states, some of which are in colour. The work as a whole ought to stimulate research in what may turn out to be a most life-saving and hopeful sphere, for Dr. Holland's conclusion is, that on the basis of the present series of 300 cases about half the number of foetal deaths are preventable—20 per cent. (the syphilitics) by ante-natal methods alone, 12 per cent. by combined intra-natal and ante-natal methods, and 20 per cent. by intra-natal methods alone. The most promising groups to attack would seem to be the complications of labour, syphilis, and the toxæmias of pregnancy.

ISOLATION HOSPITALS AND SANATORIUMS.

THERE is a touching coincidence in connexion with the publication of Dr. FRANKLIN PARSONS'S work on *Isolation Hospitals*.² The proofs of the first edition were being passed through the press in 1913 at the time of the author's death, and the task of completing the volume quite naturally fell to Dr. R. Bruce Low; to him the editors of the series of which it is a part entrusted the preparation of a second edition. This had barely left the printers before the death of Dr. Bruce Low was recorded. Although the title of the volume may give the impression that it is concerned only with the structure of isolation hospitals and with their administration, this is far from being the case, for much space is given to a discussion on their utility, to the laws regulating their erection, to the advantages and disadvantages of large and small hospitals and of combining districts for the purpose of providing a joint institution. A very helpful chapter deals with the removal of patients to hospital and with the many difficulties associated with it. For example, some local authorities are still advised by their clerks that the Public Health Act, 1875, makes it imperative on the authority to recover the cost of maintenance in an isolation hospital from the responsible person, but it is pointed out in this book that the obligation has been removed by the Public Health Acts Amendment Act, 1907. This is only one of many instances of sound practical advice which abound throughout the book and render it at once a textbook and a reliable work for reference by those engaged in public health administration.

Since the appearance of the first edition great advances have been made in our ideas as to the utility, the construction, and the administration of sanatoriums for consumptives, and Dr. Bruce Low found that he had to rewrite almost the whole of this section, though he very prudently pointed out that what he had written could only be regarded as provisional. The early belief that all cases of pulmonary tuberculosis could be treated in one institution has now been displaced by the doctrine that different arrangements are necessary for patients in the "early," "middle," or "advanced" stage of the disease. The latest plans prepared by the chief architect of the Ministry of Health are reproduced and give an excellent design for a two-story pavilion sanatorium. Illustrations of army huts at the Durham County Council's sanatorium at Wolsingham show how these buildings may be economically converted to the purposes of a sanatorium.

The final chapter contains an account, with illustrations, of certain isolation hospitals erected prior to 1911, together with particulars of their cost, which are now rather out of date. A noticeable omission from this list of hospitals is the Cambridge Isolation Hospital, which includes buildings erected at successive periods, and which show in bricks and mortar the process of evolution that has been going on as regards the planning of these hospitals, beginning with the large wards and an entire absence of single-bed wards, and ending with the small wards with glazed partitions and facilities for treating two or more diseases in one building.

ASPECTS OF DEATH IN ART.

DR. PARKES WEBER'S *Aspects of Death and Correlated Aspects of Life in Art, Epigram, and Poetry*.³ Contributions towards an Anthology and an Iconography of the Subject, is illustrated by reproductions of medals, engraved gems, ivories, and

² *Isolation Hospitals*. By H. FRANKLIN PARSONS. Second edition, revised and edited by R. BRUCE LOW, M.D., and J. E. PURVIS, M.A. Cambridge: The University Press. 1922. (Demy 8vo, pp. 231; 55 figures. 25s. net.)

³ *Aspects of Death and Correlated Aspects of Life in Art, Epigram, and Poetry*. By Frederick Parkes Weber, M.A., M.D., F.R.C.P., F.S.A. Fourth edition, revised and much enlarged. London: T. Fisher Unwin, Ltd. 1922. (Demy 8vo, pp. xiv + 851; 146 figures. 37s. net.)

antique pottery, and is dedicated to the late Sir William Osler, one of whose latest published writings was a review published in the *Annals of Medical History* in 1920 of the third edition of this encyclopaedic and scholarly work. In 1910 Dr. Parkes Weber brought out a book with a similar title which contained 160 pages and 50 figures in the text; in the present, the fourth, edition, which has really grown into a new book, there are 851 pages and 146 illustrations. Dr. Weber modestly deprecates the idea that his work contains all that has been said and could be said about the aspects of death, but though the truth of this must be admitted it would be extremely difficult to find any book nearly so complete, and it is remarkable that while so wonderfully full and detailed it is never tedious or dull. It is evidently a labour of love with the author to keep his text up to date and render it in every way worthy of his high reputation for erudition and thoroughness. As was pointed out in our review of the second edition (*BRITISH MEDICAL JOURNAL*, 1915, i, 725), this attractive anthology reminds the reader of the famous *Anatomy of Melancholy* by Democritus Junior (Robert Burton) in the profuseness and aptness of its quotations. It is divided into four parts: An introduction to the whole subject, commencing with the philosophical ideas of the ancients and ending with modern art in relation to death and a comparison of modern with mediaeval ideas. There are interesting accounts of "The Dance of Death," the *Danse Macabre*, and the *Ars moriendi*; the first of these, which probably had its origin in the thirteenth and fourteenth centuries as a morality play, contained dialogues between death and living characters typical of the various stations in life, and may have been intended by the ecclesiastical authorities to increase their worldly influence as well as to exert a religious effect. In the second and longest part of the volume the various possible aspects of death and the mental attitudes towards the idea of death are analysed and classified into a number of groups—such as the simple *memento mori* idea; death as the threshold of a future existence, in which reference is made to Samuel Butler and Maeterlinck's notion of a life before birth, with the conception of unborn souls awaiting their period of human life; survival after death in the minds of others, or posthumous fame; death as a friend, as a means of punishment, as the leveller of all mankind; for the sake of duty or honour; and from the standpoint of pessimism in regard to life. Part three contains a description of coins, medals, and medal-like tokens relating to death and to the various aspects of and attitudes towards death; it is profusely illustrated from ancient and modern sources, and brings in the satirical medals issued by the Germans in the great war. The concluding part is devoted to engraved gems, finger rings, jewels, ancient pottery, and small objects of art relating to death and to attitudes adopted towards death, and, like the rest of this wonderful storehouse of information, is admirably illustrated and interestingly written.

NOTES ON BOOKS.

DR. BUTLER'S book, *The Diagnostics of Internal Medicine*,⁴ is a comprehensive but practical treatise, which has been carefully revised for its fourth edition. The third edition was reviewed at some length in this *JOURNAL*, February 26th, 1910, page 510. In the general construction of the book an attempt has been made to follow the evolution of the physician's thought from a consideration of symptoms to an exact and accurate diagnosis. Thus the first half of the book deals with the evidences of disease and describes approved methods of examination of the body are taken in turn, and the of each sign and symptom is discussed if the book is concerned with direct and differential diagnosis. The special features of the present edition are the chapters on renal function tests, blood chemistry, and the examination of the stomach and intestines. Recently studied diseases, such as epidemic encephalitis, diverticulitis, botulism, and war gas poisoning, have also received attention. The book is generously illustrated, lucidly written, and very efficiently indexed.

Professor ROUVIER'S *Traité Pratique d'Obstétrique Normale et de Puériculture Pré- et Post-natale*⁵ is in its form the antithesis of the little book last mentioned. It is a massive quarto volume with not a single illustration. Based upon the

by G. R. Butler, M.D., Sc.D.,
and London: D. Appleton and
and 322 figures and

de Puériculture Pré- et Post-
de Clinique Obstétricale à la
Faculté de Médecine d'Alger. Paris: A. Maloine et Fils; Algiers:
J. Carbonel. 1922. (Imp. 8vo, pp. x + 832.)

lectures the author delivered during the war at Algiers, and prior to the war at Beyreuth, it is a very full and verbose description of normal obstetrics and the management of both mother and child in the puerperium and in the first year of infant life. Professor Rouvier has obviously read very widely, and through his pages are profusely scattered the names of those whom he has consulted, but as the source of their writings is not stated the value of these notes is very much diminished. We cannot conscientiously recommend this book to the student, still less to the nurse, unless they have abundance of time on their hands and take particular delight in reading French. It is unnecessarily long, and even regarded as an encyclopaedia for reference it is lacking, as we have said, in any proper bibliography. As a monument of painstaking labour on the part of the author it is most laudable.

Under the title of *L'Avenir de la Médecine*⁶ Dr. F. FRANÇON of Aix-les-Bains has translated Sir JAMES MACKENZIE'S book *The Future of Medicine*, which was reviewed at length in our columns on August 16th, 1919 (p. 204). The views expressed by Sir James Mackenzie in this work involve an indictment of existing medical methods and education. The very independence of his convictions, however, and the opposition and discussion which they aroused in this country are all the more reason why the book should be translated into foreign languages. Sir James Mackenzie's work on cardiology is known in France as well as it is in this country, and by this translation his reputation as an independent thinker in the wider realms of medicine cannot but be enhanced abroad. Dr. Françon has done his work well; his translation reads fluently in French and yet it is faithful to the original, for the real Mackenzie tang has not been lost.

We have received the first number of a new French monthly publication, entitled *Clinique et Laboratoire*, described as an international review of the medical and pharmacological sciences. The first number contains papers by Dr. Nobécourt on the bronchi changes in typhoid fever, on the prophylaxis of influenza by Dr. Sézary, and on the serum treatment of pneumonia by Dr. Albert. Abstracts from current literature are devoted to diseases of the digestive, circulatory, and respiratory systems, tuberculosis, syphilis, endocrine glands, and biology.

The *Transactions of the Second International Conference on Tuberculosis*,⁷ held under the auspices of the British National Association for the Prevention of Tuberculosis in London, in July, 1921, have been published in a volume of 264 pages. A report of the proceedings of the conference was published in our issues of July 30th and August 6th, 1921.

⁴ *L'Avenir de la Médecine*. By Sir James Mackenzie. Translated by Dr. Françon. Paris: F. Alcan. 1922. (Demy 8vo, pp. 272; 28 figures. Fr. 12 net.)

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

SCOTTISH SMALL CAR TRIAL RESULTS.

THE Royal Scottish Automobile Club has completed the checking of the calculations in connexion with the six days' 1,020 miles international Small Car Trials for strictly standard vehicles, June 5th to 10th inclusive, the facts being the first indisputable ones available to the buying public in comparative fashion. Applications should be made to Mr. Robert J. Smith, Secretary, 163, West George Street, Glasgow, for a copy of the very interesting detailed report. In this connexion it must be understood that the route was much more severe, especially in regard to gradients climbed, than the average district covered by a medical man. But the weather was good throughout the test, otherwise some of the vehicles would have lost marks through becoming stuck in the more slippery surfaces of the steepest, worst foundationed hairpin and other abrupt turns. The fuel consumption figures are also notable, though, of course, the final award under this head did not go to the car making the best showing in the timed hill climbs and other speed tests. Therefore attention should be directed to the fuel consumption of those vehicles which did well under those heads. They will be found to be, proportionately, no less excellent. Another interesting point is that the Talbot-Darracq standard products here represented are no less successful in competition with other standard machines than the special vehicles of the make which have carried all before them in their categories in track and road tests at home and abroad, including the French Voiturette Grand Prix and the "Fifteen Hundred Trophy" in the Isle of Man last week, thereby giving a

complete and sufficient answer to criticism. As for the air-cooled car, the Scottish Trial shows that, under all heads, it scored in the cheapest category only. No gold medal was awarded for a class performance unless the given vehicle scored at least 90 per cent. of the maximum marks attainable alike for reliability and for hill climbing. The gold medals have accordingly been awarded as follows:

Class A vehicles, the complete selling price of which does not exceed £250:

To A-19, 9 h.p. Stonleigh, entered by Stonleigh Motors, Ltd., Coventry, and driven by Mr. E. J. Herbert, which gained 926.255 marks.

Class C vehicles, the complete selling price of which exceeds £325, but does not exceed £420:

To C-8, 8 h.p. Talbot, entered by Clement-Talbot, Ltd., Ladbroke Grove, London, and driven by Mr. H. G. Day, which gained 945.4 marks.

Class D vehicles, the complete selling price of which exceeds £420, but does not exceed £500:

To D-23, 11.9 h.p. Star, entered by the Star Engineering Company, Ltd., Wolverhampton, and driven by Mr. R. Lisle, which gained 983.05 marks.

Class E vehicles, the complete selling price of which exceeds £500:

To E-31, 11 h.p. Riley, entered by Maxlee Motor Company, Edinburgh, and driven by Mr. Herbert Anderson, which gained 987.45 marks.

Silver medals, under the conditions, fall to be awarded to each car making full marks for non-stop and reliability. Silver medals have consequently been gained as follows:

Class C: By C-25, 10.5 h.p. Galloway, entered by Galloway Motors, Ltd., Tongland, Kirkcudbright, and driven by Mr. V. Leverett. By C-41, 10 h.p. G.N., entered by G.N. Motors, Ltd., Wandsworth, London, and driven by Mr. L. A. Cushman.

Class D: By D-26, 10.5 h.p. Galloway, entered by Galloway Motors, Ltd., Tongland, Kirkcudbright, and driven by Mr. W. Barber.

Class E: By E-13, 12 h.p. Talbot-Darracq, entered by Darracq Motor Engineering Company, Ltd., and driven by Mr. G. Griffiths.

By E-31, 11 h.p. Riley, entered by Maxlee Motor Company, Edinburgh, and driven by Mr. Herbert Anderson.

All five vehicles gained the maximum number of marks—namely, 750—for non-stop and reliability.

In respect of meritorious performances, the Trial Committee have awarded a merit gold medal to B-14, 7 h.p. Wolseley, entered by Wolseley Motors, Ltd., Birmingham, and driven by Mr. L. A. Illiston; and have awarded merit silver medals to E-12, 12 h.p. Talbot-Darracq, entered by Darracq Motor Engineering Company, Ltd., Acton, London, and driven by Mr. M. L. Livings; to B-5, 11 h.p. Lagonda, entered by Lagonda, Ltd., 195, Hammersmith Road, London, and driven by Captain W. H. Oates; and to G-7, 10 h.p. Swift, entered by Charles H. Jones, 108, Lothian Road, Edinburgh, and driven by Mr. Charles H. Jones and Mr. A. Alexander.

A special award for the most meritorious team performance has been made to the Darracq Motor Engineering Company, Ltd., Acton, London, in respect of the performances of two 12 h.p. Talbot-Darracqs, driven by Mr. M. L. Livings and Mr. G. Griffiths respectively.

The Scottish Cup, for the vehicle showing the lowest fuel consumption per ton-mile over the whole trial, has been gained by C-47, 11.4 h.p. Citroën, entered by Gaston, Ltd., Acton Vale, London, and driven by Mr. R. A. Richards, with a consumption of 0.04232 gallon per ton-mile, equal to 41.112 ton-miles per gallon of fuel.

MEDICAL AND SURGICAL APPLIANCES.

Twin Tonsil-bed Compressor.

MR. G. GUSHUE-TAYLOR, M.B., B.S., F.R.C.S. Eng. (Girls' Village Home, Barking, Essex), writes: After removal of the tonsils most surgeons, before looking for the individual vessels, will apply pressure by means of sponge-holding forceps, and most commonly will use two pairs of forceps crossed, exerting pressure on the tonsil-bed. This pressure kept up for a few minutes usually suffices to stop bleeding. I have recently devised an instrument which mechanically exerts the pressure of the operator's hands. The instrument, a "twin tonsil-bed compressor," is made of two sponge-holding forceps bent at an angle a short distance from the tip, so that when jointed together, approximation of the handles causes separation of the blades, which, holding gauze swabs or sponges, press on the tonsil-bed. When applied, the handles are locked by a simple device of a screw and nut fixed to one handle inserted into a slot on the other. The length of this bolt screw pressure exerted on the bleeding area, made, easily applied and removed, light position when applied, and can be used for days returned to bed. While the idea was added some mechanical devices which increase its efficiency.

MEMORIAL TO SIR G. S. WOODHEAD.

WE have received for publication an appeal for subscriptions to a proposed memorial to Sir German Sims Woodhead, K.B.E., M.D., late Professor of Pathology in the University of Cambridge. It is proposed that the memorial shall take the form of a portrait relief in bronze, to be placed in the library of the Medical School at Cambridge, and that it shall correspond in design to those of Professor Woodhead's predecessors in the Chair of Pathology, the late Professors Roy and Kanthack. The signatories to the appeal, whose names are given below, write as follows:

The proposed Memorial would consist of a slightly over life-sized portrait bust of bronze in low relief (the tablet 2 ft. 6 in. by 2 ft.) bearing the inscription, "Sir German Sims Woodhead, K.B.E., M.D., Professor of Pathology, Cambridge, 1899-1921." It is suggested that, if sufficient funds are collected, a reduced copy of the Memorial in bronze (measuring 9 in. by 7 in.) shall be presented to Lady Woodhead.

We propose to put the execution of the Memorial Tablet into the hands of Mr. John Pinches, who will work mainly from a photograph (a copy of which is reproduced) selected as the most suitable for the purpose, and which represents Sir German as his friends knew him at his best, and before the heavy work and responsibilities which the war threw upon him had undermined his constitution.

The cost of the Memorial, including its erection in the Medical School, and that of the replica, is estimated at £125, allowing for contingencies. If the subscriptions exceed the amount required, we suggest that the surplus shall be applied to the purchase of books for the Medical School Library, to which, during his life, Sir German contributed so liberally.

It is thought probable that many persons would like to possess a reduced copy of the memorial plaque. If a sufficient number of persons intimate their wish to do so reductions will be made in two sizes.

The cost of these to subscribers would be: (1) Mechanical reduction, 9 in. by 7 in., bronze cast, £3 10s.; copper electrotype, £2 10s. (not including frames or mounts); (2) small bronze plaques struck from a steel die, 2½ in. by 2 in., £1 10s.

Subscriptions to the Memorial Tablet (not exceeding 1 guinea) may be sent to the treasurer, Dr. L. Cobbett, Medical School, Downing Street, Cambridge. The names of the subscribers will be printed and circulated when the list is closed.

We appeal with confidence to the many, whether colleagues, students, or laymen, whom Sir German befriended and helped in his characteristic self-sacrificing manner, to aid us in erecting this affectionate tribute to his memory.

(Signed) Rt. Hon. Sir T. CLIFFORD ALBUTT, P.C., K.C.B., M.D., F.R.S., Regius Professor of Physic, Cambridge.

Sir HUMPHRY ROLLESTON, K.C.B., M.D., President of the Royal College of Physicians, London.

Sir RICHARD ANDERSON, M.D., F.R.S., Chairman of the Special Board for Medicine, Master of Gonville and Caius College, Cambridge.

H. BOND, LL.D., Master of Trinity Hall, Cambridge.

Rev. W. B. SELBIE, D.D., Principal of Mansfield College, Oxford.

J. G. ADAMI, C.B.E., M.D., F.R.S., Vice-Chancellor of the University of Liverpool.

J. LORRAIN SMITH, M.D., F.R.S., Professor of Pathology, University of Edinburgh.

J. RITCHIE, M.D., F.R.C.P. Edin., Irvine Professor of Bacteriology, University of Edinburgh.

ROBERT MUIR, M.D., F.R.S., Professor of Pathology, University of Glasgow.

Rev. H. C. CARTER, M.A., Minister of Emmanuel Congregational Church, Cambridge.

Prof. G. H. F. NUTTALL, Sc.D., F.R.S., } Hon. Secs.

British Medical Journal.

SATURDAY, JULY 1st, 1922.

THE CAUSES AND PREVENTION OF FOETAL DEATH.

DURING the past few years a determined attempt has been made to discover and classify the causes of the death of the foetus, and the attempt is still going forward. The Ministry of Health has made known Dr. Eardley Holland's report on the factors which determined death in 300 foetuses of viable age obtained from London hospitals, a research which was mostly accomplished before 1917, when the author went to France in the R.A.M.C. Under the Medical Research Council a number of skilled workers have been engaged since the war in examining series of stillbirths occurring in some of the large towns of this country, including London, Edinburgh, Glasgow, Liverpool, and Cardiff; and in part their results have been published or are being prepared for publication—for example, those of Dr. F. J. Browne¹ in Edinburgh and of Dr. A. M. Kennedy in Glasgow, now Professor of Medicine at Cardiff. In America, also, work under Whitridge Williams and others has been going on. Finally, at the Annual Meeting of the British Medical Association in Glasgow there is to be a discussion on intrauterine death, in which many of those who have been engaged in these researches will take part, and from which it may be expected that conclusions regarding causation and treatment will be forthcoming. Meanwhile, from the results already made known some things may be learned.

Holland's work, reviewed on page 16, prepares the way for a clearer conception of the problems involved, and also contributes much to their elucidation. Foetal death, for instance, is defined as the cessation of the heart beat, and it is pointed out that this may happen during the ante-natal time, in the intra-natal period, or in the short post-natal time which elapses between the birth of the foetus and the beginning of pulmonary respiration. An extension of the significance ordinarily given to the term foetus is thus established, but the change works for clearness of thought—no small advantage in the study of the death of an organism which in the legal sense is not yet, strictly speaking, alive. Dr. Holland has also rendered good service by distinguishing between the primary causes of foetal death and the "consequent factors"—between placenta praevia, for instance, as the primary cause, and separation of the placenta leading to foetal anaerobiosis as a consequent factor. It may be frankly admitted that the inter-relationship between primary and consequent factors is as yet by no means fully understood, and that the whole subject of foetal death is, on the side of pathogenesis, a most intricate and baffling problem. Even when the primary cause is interference by the obstetrician during the act of labour the mode of its operation and the mechanism by which the result is brought about are often obscure. There is, for example, the extraordinarily interesting effect of pressure on the foetal head by forceps or by the walls of a contracted maternal pelvis. Holland opens up new avenues for thought when he suggests that the intracranial septa have the function of enabling the head and its contents to resist excessive stress during its passage through the mother's canals. Cranial stress may, however, be too great, and the septa (for example, the tentorium cerebelli) may give way,

intracranial haemorrhage then follows, and death during birth or soon afterwards ensues.

Another new line of investigation which promises to throw light upon certain morbid conditions discovered at birth has been suggested and begun by F. J. Browne.² It has long been known that the eyes of the foetus may become infected with gonococci during birth, but Browne has shown that if the foetal membranes be ruptured for a number of hours in labour other microbes, such as the pneumococcus, may invade the organs of the infant and produce diseases, such as pneumonia, which are found in active progress at birth and which may cause death then. It is conceivable that it may turn out that a group of such intra-natal maladies may be revealed, all of them of profound importance in the causation of early post-natal deaths, and all of them, let it be noted, capable of being prevented. To name only one other result of the work of Holland and Browne, it has been discovered that syphilis is hardly so great a cause of stillbirth as had been assumed by the Royal Commission on Venereal Diseases. Both these observers find that among the causes of stillbirth syphilis accounts for something like 16 or 17 per cent. It has, however, to be remembered that miscarriages are not included, so that whilst syphilis may account for only a comparatively small number of stillbirths, it may be fatal in a larger degree when regard is had to the whole duration of ante-natal life.

The prevention of foetal death, far from being a hopeless task, is a most promising subject. Holland's statement that "ante-natal methods are the strategy, whilst intra-natal methods are the tactics, of obstetrics" is not simply a piece of brilliant phrasing: it is the setting forth of the sober and the attractive truth. An analysis of the causes of death in the 300 cases of foetal death investigated by Holland (and the same holds true of Browne's 200) shows that half of them were preventable. Ante-natal treatment of syphilis could prevent 16 per cent.; the ante-natal and intra-natal treatment of the toxæmia of pregnancy could prevent 6 of the 10 per cent. due to that cause; the ante-natal, but chiefly the intra-natal, treatment of the complications of labour could prevent 30 of the 51 per cent. caused by pelvic contraction and *ante-partum* haemorrhage; and 1 out of 2 per cent. due to chronic renal and other maternal diseases could in all probability be saved by ante-natal management. Of the 22 per cent. due to undeterminable causes, to foetal deformities, and to relative placental insufficiency and retroplacental clot, Holland does not allow that any part could be saved. The employment, therefore, of ante-natal supervision and treatment in pregnant patients, combined with a rational application of the information thus gained to intra-natal methods of management of birth, should reduce the percentage of stillbirths by about a half. This is a very remarkable forecast, and if even a part of the saving is attained, thousands of young lives will be in the way of being saved. In the order of their hopefulness attempts to deal with the complications of pregnancy, with syphilis, and with the toxæmias of pregnancy, seem to invite immediate action. The first thing to be done is to correlate the information now being obtained through the ante-natal work with the conduct of the labours following upon such pre-natal supervision.

THE PLIGHT OF THE RUSSIAN MEDICAL PROFESSION.

"THEREFORE shall her plagues come in one day, death, and mourning, and famine." Those of our readers who read the report of its Proceedings printed in last week's SUPPLEMENT will be aware that the evidence brought before it at its last meeting satisfied the Council of the

¹ BRITISH MEDICAL JOURNAL, July 30th, 1921, p. 140.

² BRITISH MEDICAL JOURNAL, March 25th, 1922, p. 469.

British Medical Association that the reports to the effect that medical men and their families are starving in various parts of Russia are true. Our paragraph on this subject stated that the Council had very carefully considered an appeal from the Russian Pirogoff Medical Society for help for the Russian medical profession in its terrible plight. This pathetic appeal had been forwarded to the Association by the Russian Committee for Famine Relief, and was reinforced by communications from Russian medical men in this country, among them Professor Korenehevsky of the Lister Institute, who is chairman of the Russian Academic Group in Great Britain. This was the first attempt to get the medical profession in other countries to come to the help of the profession in Russia. The Russian medical societies have done their best to help their own colleagues; but they have now come to the end of their resources. The conditions by all accounts are appalling.

In turning a sympathetic ear to an appeal so tragic the Council has, we feel sure, interpreted the feeling of the Association and the British medical profession at large. The appeal is for the only form of aid which in the circumstances can be effective—namely, the sending of food parcels through the American Relief Administration to individual doctors and to groups for distribution among their members in greatest need. The only question debated by the Council was the manner in which this appeal should be put forward; for all were agreed that this was a case for prompt action, and an appeal to which every medical practitioner in this country ought gladly to respond. It was unanimously resolved that a direct appeal should be addressed to every member to send a subscription of five shillings. It was felt that this limitation to a small sum would go far to secure an immediate and widespread response. Steps were at once taken to act upon this resolution, and an urgent appeal, signed by the four officers of the Association, is now being issued to members. The text of the appeal is printed at p. 26.

We have been asked to bring the matter forward prominently in the JOURNAL, and we gladly do so. This is no occasion for delay in well-doing. The Medical Secretary has in his hands a list of Russian doctors, and families of deceased doctors, to whom food parcels must be sent at once if they are to be saved from death by starvation. The parcels, as we have said, will be forwarded through the American Relief Administration in London, which makes itself responsible for their delivery to the persons addressed, and obtains a receipt from them showing that the parcels have reached the persons for whom they are intended. Nine subscriptions of five shillings each will more than cover the cost of one parcel, including all charges. Contributions should be addressed to the Financial Secretary of the Association, 429, Strand, W.C.2, who will send a receipt. It will not be possible to acknowledge all the names of subscribers in our columns, but the amount of money collected will be announced from time to time. We feel sure that as soon as this desperate need is known our readers will respond. In an emergency of this kind questions of politics and nationality are forgotten.

THE LAST HIGH CLIMB ON EVEREST.

THE Mount Everest Committee has received further news from the expedition, and a report from General C. G. Bruce embodying an account by Mr. Finch of the climb by Captain Bruce and himself, using oxygen, to 27,300 ft. on Mount Everest was published in the *Times* of June 24th. It is a narrative of splendid courage and resource in overcoming endless difficulties and dangers. It also illustrates, if possible even more clearly than the narrative of Mr. Mallory, on which we commented last week, the extraordinary powers of

adaptation of the human organism. The most significant fact in this connexion was that a number of native porters, carrying weights up to over 30 lb., were able to climb to 25,500 ft. and repeat the climb next day. Not one of them came to any harm. It was said ten years ago by the members of the Pike's Peak expedition that there seems to be no physiological reason why an acclimatized person should not climb Mount Everest without oxygen; and the recent experiences bear out this inference. Messrs. Finch and Bruce were provided with oxygen apparatus, which they used in a modified form during their climb. The compressed oxygen was carried on their backs in very light steel cylinders of the type constructed for the Royal Air Force and Royal Army Medical Corps during the war. Although these cylinders had done splendid service, and without, so far as we know, any accident from bursting, they were condemned as insufficiently safe for ordinary purposes. A supply of fully charged cylinders was, however, obtained for the expedition from the Royal Air Force, and this made the use of oxygen possible. It was out of the question to use the ordinary extremely clumsy cylinders, which make the efficient use of oxygen so difficult for medical purposes. To judge from a photograph which has been published, the oxygen was intended to be added to the inspired air in a face-mask of a Royal Air Force pattern. This mask is also fitted with an "economizer" arrangement similar in principle to that used for medical purposes, and described in its first form by Dr. J. S. Haldane in the *BRITISH MEDICAL JOURNAL* of February 10th, 1917. By this arrangement the consumption of oxygen is reduced to half what would otherwise be needed. The airman's apparatus was, however, designed for the use of unacclimatized persons, and as soon as it was tested by Mr. Finch after he was acclimatized at 21,000 ft. the air supply through it was found to be quite insufficient. There was no alternative but to discard the face-piece and take the oxygen through a rubber tube straight into the mouth, though this reduced the efficiency of the oxygen to half. Even with the reduced efficiency the benefits of the oxygen were very noticeable, but they seem to have been completely counterbalanced by the weight of the oxygen cylinders carried. In the final climb from the camp at 25,500 ft. the Gurkha N.C.O. Tejbir had 48 lb. to carry, while Finch and Bruce had 36 lb. At 26,000 ft. Tejbir broke down in spite of the oxygen. Finch and Bruce took his spare cylinders and pushed on with a weight of 48 lb. each. It was a "cruel imposition"; but they nevertheless got 1,300 ft. higher, in spite of the weight and insufficient oxygen supply. At this point the glass tube used in connecting up Bruce's oxygen tube broke without their noticing it at first, and Bruce could no longer cope with the weight. The tube was soon mended, but they very wisely went no farther. When they got down to the camp at 21,000 ft. they were absolutely exhausted, and all, we gather, more or less frostbitten. It is unfortunate that the present expedition was not provided with the means of investigating in any detail the very interesting physiological adaptations at high altitudes. In the expedition last year Dr. Kellas had everything needed for carrying out a number of observations, but owing to the calamity of his death—which occurred while, owing to illness, he was being carried by natives over a pass—the observations were never carried out. He had intended to ascertain how much the breathing is increased at very high altitudes; and from the data obtained it would have been possible to plan this year's attempt far more scientifically. Enough, however, was known from the data of the Pike's Peak expedition to show that it would be necessary to allow for an enormous increase of the breathing. Even on Pike's Peak the breathing was increased during climbing at a moderate rate to fourteen times the resting value at sea-level. The decision that oxygen should be used by the present expedition in climbing was reached very shortly before it left England, and for this reason, apparently, there was no time to consult physiologists about the apparatus. Owing to the monsoon no further attempts can be made this season; but the great achievements of the

present expedition have shown clearly that it is possible to reach the summit of Mount Everest by climbing. We hope, however, that in any future attempt due provision will be made for investigating the physiological problems of life at very great altitudes.

THE GROWTH OF THE GENERAL PRACTITIONER.

We are indebted to Dr. Arnold Chaplin for the following note: "The study of the history of medicine has come into considerable prominence during the last two decades, and now this country may be said to possess a definite school of thought devoted to the subject. The time is not far distant when those interested in the history of medicine were regarded as amiable people engrossed in an innocent hobby, which, while it did no harm, was certainly of very little practical utility. Dr. John Freind, that learned and admirable physician, was the first in this country to write early in the eighteenth century, a history of medicine, and although we have travelled a long way since then, his work may still be consulted as an accurate guide to the history of medical endeavour during the period of which his book treats. After that the subject remained dormant in this country until John Aikin published his *Medical Biographies* in 1780, and from then onwards the history of medicine was confined to the biographical side. In this branch much valuable work was accomplished by Dr. Munk, who compiled the Roll of the Royal College of Physicians of London, Sir Norman Moore, and Dr. Payne. Lately, however, the history of medicine has been approached from a wider point of view, and now, largely owing to the work of Dr. Siiger, the whole wide field of the history of medical and scientific ideas is being investigated with the prospect of a certain degree of finality being reached. But, although most of the various branches of medical history are receiving attention, an exception must be made in the case of the history of the origin of the various grades in the profession, and of the laws and regulations promulgated from time to time for the protection of those grades. Dr. N. G. Horner has recently supplied this omission. In an essay submitted as a thesis when taking the degree of M.D. at Cambridge and printed for private circulation, he has dealt with the important question of the rise and development of the general practitioner. The materials for this account are scanty and difficult to find. Indeed, with the exception of the work of John Masou Good, there seems to be no book dealing specifically with the subject, and even that work is deficient in many important respects. Dr. Horner has made a diligent search for the facts upon which he has founded his essay, and now we have for the first time a connected account of the development, rise, and progress of the grade of the general practitioner, together with a history of the laws and regulations made from time to time for its protection. This is admirable pioneer work; Dr. Horner will do well to continue his researches in the future. Although there is evidence that the grade of general practitioners was gradually being evolved, it was not until the passing of the 'Apothecaries Act' in 1815 that they became a definite body. This 'Charter' of the General Practitioners, as it may be termed, was the first of the medical Acts, and had far-reaching effects. The two Colleges had their charters and regulations, but they dealt with comparatively limited numbers. The Apothecaries Act, however, regulated the education and actions of by far the largest part of the profession, and although the Medical Act of 1858 took away from the Society of Apothecaries most of the powers conferred by the Act of 1815, the principle remained, and has been instrumental in welding together the finest body of general practitioners that any country can produce. The history of the development of any particular grade in the medical profession can only be known by a study of the legal enactments regarding the medical profession as a whole. This branch of the history of medicine is rarely studied, although much of the early history of medical laws and charters can be found in an admirable book written by Wilcock and published in 1830. The whole subject, however, is worthy of study,

and it is to be hoped that Dr. Horner, who from his position is peculiarly qualified to perform the task, will direct his abilities to a consideration of that branch of the subject."

THE NATIONAL PHYSICAL LABORATORY.

THE annual report of the National Physical Laboratory for the year 1921¹ has reached us this week. It contains an account of the work done during the year and indications of what is to be done during this year. Perhaps the most impressive pages are those containing a list of the staff working in the several departments of the Laboratory under the general supervision of Sir J. E. Petavel, K.B.E., F.R.S.; the Director, who is also the superintendent of the Physics department. The other departments are devoted to electricity, metrology, engineering, aerodynamics, metallurgy and metallurgical chemistry; in addition there is a special staff for the William Froude National Tank for experiments on the designing of ships and on their propulsion. The list of papers published by the Laboratory during 1920 and 1921, or communicated by members of the staff to scientific societies or technical journals, is also impressive, for it fills eight pages. In the Radiology Division of the physics department both radium and x rays are investigated; during the year the Division was installed in new premises at Elm Lodge, and, in spite of vibration troubles, the increase in space is found to add much to the efficiency of the working. An examination of radium contained in sealed metal tubes has rendered it possible to work out tables of correction for tubes full and partly full, and having different wall thicknesses and external diameters. The methods of measurement of the intensity of x rays are being improved, and an investigation has been made into the absorptive qualities of different samples of lead-glass, lead-rubber, and various compositions of heavy materials. The "lead values" (that is, the thickness of lead equivalent in absorbing power to one millimetre of the specimen) of different samples of lead-rubber varied between 0.1 mm. and 0.45 mm. Lead-glass is found to have on the average a rather smaller lead value, varying between 0.1 mm. and about 0.3 mm.; compositions of various kinds gave values up to about 0.4 mm. Lead-rubber tends to deteriorate with time, especially if the amount of opaque salt with which it is impregnated is out of proportion to the amount of rubber. For some purposes, therefore, the best material may not be that most heavily loaded with salts, but one which, while giving good density, has sufficient rubber in it to preserve it from unduly rapid deterioration. An X-ray and Radium Protection Committee, appointed to inquire into the degree of protection afforded by different x-ray protective appliances used in connexion with x-ray installations, has presented a preliminary report, and has made certain specific recommendations, which, it is stated, are being widely acted upon. The Laboratory has agreed to examine x-ray installations, and a number of hospitals have availed themselves of the facilities offered. The Director states that there is little doubt that the majority of the x-ray installations in this country are deficient from the point of view of protection, for stray radiations can generally be found in abundance throughout the x-ray room. Another matter to which the Division has given attention is the use of the barium platinocyanide pastille as an intensity measurer. It was found that the ionization method of measuring the intensity of a beam of x rays corroborated in every instance the results obtained with the pastille when the change of tint of the pastille was measured by means of a tintometer. Certain improvements in this instrument have already been made, but a few more refinements will be necessary before it can be put into use. The product of the ionization per minute—ascertained by the electroscope, and the time of dose—given by the pastille (that is the time taken to change the colour of the pastille from one fixed tint to another) proved to be a constant independent of the current

¹ London: H.M. Stationery Office, or through any Bookseller. Price 6s. 6d.

through the tube, type of interruptor, frequency of interruption, interval between "make" and "break," and voltage of the primary current. These results have led to a simple method of testing the barium platinocyanide pastille after the standard dose has been established. Further investigations are being made, and it was hoped at the time the report was published that it would be possible very soon to undertake the testing of barium platinocyanide pastilles with unfiltered radiation.

STRUCTURE AND FUNCTION OF THE STOMACH.

At the summer meeting of the Anatomical Society of Great Britain, held in Edinburgh at the close of last week, Mr. Geoffrey Jefferson, of Manchester, read a paper entitled "Some remarks on the anatomical structure of the stomach, with special reference to gastric function." After a brief description of the mucosa the speaker passed on to the musculature, of which he had made numerous dissections. There is no account of this musculature in the English language which can be correlated with the x-ray and physiological findings of stomach posture and digestion. Mr. Jefferson referred to the work of Förssell, whose findings agree closely with his own. Special attention was paid to the thickenings of the external longitudinal coat at the pylorus, the ligamenta pylori, with their strong adhesion to the circular fibres beneath. These form important intrinsic supports to this region and are plentifully interspersed with elastic tissue. The circular musculature was seen to consist of interwoven fibres and not of rings applied in contiguity. This arrangement was to be expected since the best evidence showed that the peristaltic wave was myogenic in origin and flowed from band to band. The connexions of the oblique muscle were next figured. This coat was seen to be a derivative of the circular muscle. The laying down of a third coat over the cardiac portion of the viscus required some explanation, for in the alimentary canal in general the processes of digestion are completed by two coats, an inner circular and an outer longitudinal. For what reason should the stomach have three, and why should the added third coat be laid down over a part of the stomach which is relatively inactive in peristalsis? Mr. Jefferson believes the answer to be that this coat is largely suspensory in action—that the gastric musculature has two functions: the first is that of rhythmic contraction (that is, peristaltic or phasic), the second is static or postural. These activities may be interchanged according to the needs of the case, or, indeed, may both be carried on at one and the same time. Thus peristalsis may become a feature of the fundus of the stomach in recumbency where food has to be passed along against the action of gravity.

SMALL-POX AND VACCINATION IN THE PHILIPPINES.

ONE or two recent questions in Parliament have called attention to this matter, which is dealt with in the Report of the Philippine Health Service for 1920. The Report for 1921 does not seem to have been yet issued. The population of the Philippines is about nine millions, including nearly 300,000 in the capital city of Manila, but not including some half-million in the southern islands, Mindanao and the Sulu archipelago. The statistics of small-pox prevalence and fatality are extraordinary.* In 1919 in the provinces there were recorded 60,612 cases with 43,294 deaths, or 71 per cent. What are called "relatively insignificant figures" for 1920 consisted of 10,448 cases with 4,386 deaths, or 42 per cent. In the southern islands, three provinces had in 1919 a total of 4,511 small-pox cases with 1,075 deaths, or 25 per cent., and in the following year 5,404 cases with 2,805 deaths, or 52 per cent. In the city of Manila small-pox had been practically absent for about nine years up to 1918, when there occurred 1,326 cases, but the number of deaths does not appear to be mentioned in the only report we have seen. The

epidemic in Manila was, however, brought to an end within the year, there having been only 57 cases in 1919 and 5 in 1920. Next as to vaccination, small-pox appears to have given the usual stimulus to the practice. In the provinces, in two and a half years from the middle of 1918, about 4,300,000 vaccine units "had been distributed," with an "estimated positive result of 77 per cent." The negative results would therefore be 23 per cent. Elsewhere in the Report it is stated that in 1920 (included in the two and a half years) the total vaccinations were 3,222,460, of which 1,399,985 were positive, or 63.58 per cent., leaving a failure rate of no less than 36 per cent. These are remarkable figures, but they are not nearly so bad as for the southern islands, where only 10 to 15 per cent. of vaccinations had a positive result. The explanation given is that a trained staff was not available, and that there were difficulties in transporting the vaccine virus. But the effect of the high rate of failures on the mind of the vaccinators seems to have been disastrous. We are told that a "pulverized small-pox vaccine prepared by the Bureau of Science" has been adopted, and that "a complete success was obtained with the use of this kind of vaccine, according to the reports submitted by the district health officers, who estimated that 70 per cent. of the vaccinations gave positive results." Thus it turns out that a 30 per cent. failure is acclaimed "a complete success." The fact is that the whole subject of small-pox and vaccination in the Philippines requires thorough and competent investigation. In Parliament a member asked the Minister of Health whether he would not cause special inquiries to be made into the outbreak, but obviously the duty lies with the U.S.A. Federal Government, and we have no doubt that it will be adequately discharged. The small-pox fatality rates given in the Report are greater even than amongst the unvaccinated in the hospitals of the metropolis in the pandemic of 1870-73, the most virulent in Europe within living memory. The Philippine Islands are very well isolated by nature, but even so it is important to know whether the extraordinarily mild small-pox which the United States, Canada, South Africa, Australia, and Britain have experienced in recent years may now by any even remote possibility be displaced by a type of such severity as has not been seen in any white man's country since that which followed the Franco-Prussian war. Equally the United States will need to inquire into the whole practice of vaccination in the Philippines—the preparation, preservation, and distribution of vaccine material, the method of vaccinating, and the competence of the vaccinators. These, however, are primarily matters of domestic concern. The knowledge which Europe has gathered during the past hundred and twenty years of the effect of vaccination in controlling small-pox will in no degree be diminished in value by any extraordinary occurrences in the course of prophylaxis as practised in the Philippines.

CO-OPERATIVE HYGIENE.

IN his presidential address¹ to the Southern Branch of the Society of Medical Officers of Health Surgeon Commander R. J. MacKeown, Naval Health Officer, Portsmouth, made a plea for closer co-operation among all health officers—civil, naval, military, and air force—with a view to safeguarding the health of the civil and service populations in time of peace, and to preserving a high standard of health among the forces mobilized in any national emergency. He pointed out that since the armistice the Admiralty had not been backward, and had appointed naval medical officers with special knowledge of hygiene as health officers to the great naval ports—Portsmouth, Chatham, Devonport, and Rosyth. These officers were on the staff of the respective commanders-in-chief, and their duties were to ensure the health of the naval population, to investigate outbreaks of disease, to assist the principal medical officers of the port, and to recommend measures for preventing the spread of disease in the commands. In Portsmouth an excellent understanding had been built up between the civil and military officers of

* The gross figures were given by the Minister of Health to the House of Commons (BRITISH MEDICAL JOURNAL, April 8th, p. 579). The details in the report render it possible to analyse them a little further.

¹ Public Health, June, 1922, p. 245.

health in the command area and the naval health officer, and the chain of supervision and prevention was such that although six limited outbreaks of small-pox occurred in the command during 1919 and 1920 only one case occurred among the naval population; the disease was contracted in Portugal by a homeward-bound member of a drifter's crew. Surgeon Commander MacKeown thought it would be most advantageous if county councils would take up the question of a county sanitary survey, with a view to military exigencies. To apply this principle to small-pox he suggested that there should be set apart in each county a well-equipped and suitably placed hospital for the reception of cases and suspects. To such a hospital would be sent all cases which occurred in the county, whether civil, naval, military, or in ships arriving from overseas. Recent information should be available regarding such matters as camp sites, billets, water supplies in existence or projected, drainage and conservancy arrangements, accommodation for cases of infectious disease and contacts, and laboratories for bacteriological and other examinations. Notifications of communicable diseases should be reciprocal, and mutual assistance given in dealing promptly with such cases. He considered it most important that notifications should be prompt, and should apply not only locally, but to any place where service men might be proceeding or had dwelt while on leave. All disinfecting plant, irrespective of authority and situation, should be available whenever necessary. Measures for the prevention of such diseases as small-pox and venereal disease must not only be promptly taken but continuously maintained; by such co-operation as was suggested preventive medicine might become an active force in the production of individual fitness among those called upon to undertake the defence of their country at home, abroad, and at sea.

ASSESSMENT TO INCOME TAX OF FEES HANDED ON TO LOCAL AUTHORITIES.

ONE of the early leading cases on the income tax, quoted as the *Mersey Docks and Harbour Board v. Lucas*, laid down the general principle that if any particular income was liable to assessment as being within the description of chargeable income, its taxability was independent of its destination, subject to the specific exemption in favour of charitable bodies. A correspondent has drawn attention to the fact that a rigid insistence on this principle works unfairly when applied to a medical man engaged on a whole-time basis by a local authority. If in such cases he is to be assessed to income tax for the fees which he hands over to the authority as well as for the salary he receives from the authority, the result is that the total amount assessed is greater than the gross amount of his earnings—and that remains the case even if he hands over only the net amount of the fees after deduction of the income tax. To the extent to which the medical officer devotes his time to work which produces fees from other sources he ceases to do the work for the salary for which he is assessed—at least that is the assumption underlying the clause in his agreement which provides that such fees must be handed over—and we conceive that he should not be assessed for the earnings unless they are clearly additional and not substitutionary. It would seem that in the case of our correspondent sufficient weight has not been given to the fact that the agreement for service is the very instrument under which the fees have to be handed over. The only income assessable is that of the medical officer, and since it is a condition of his employment that other earnings have to be handed over, it seems to us that there is good ground for claiming that the payment of those sums to the authority should be regarded as expenses wholly, exclusively, and necessarily incurred in the performance of his duties; they were payments which he was bound to make in performance of the contract of service under which he receives the salary for which he is assessed. Whether that point was put to the Commissioners on appeal we do not know, but in any case it might be worth taking up if another practitioner should find himself in a similar unfortunate position.

THE CHALMERS LIBRARY.

THE collection of books from the library of the late Dr. Albert J. Chalmers, presented by his widow to the Royal Society of Medicine, contains about 1,800 volumes in all. It includes five volumes printed before the end of the fifteenth century, 64 printed in the sixteenth century, and 109 in the seventeenth century. The books he had collected fall into two parts—the early books already mentioned, and the remainder relating to the subject in which he was specially interested. Dr. Chalmers was at one time Director of the Wellcome Tropical Research Laboratories (Sondan) and was joint author with Dr. Castellani of the large *Manual of Tropical Medicine*. Among the older volumes are several fine herbals, including a fine copy of that issued by Fuchs in 1543 and by Brunfels in 1546. There is also Turner's *Great Herbal*, 1568, printed in Cologne, probably compiled by the author during his residence there. There is a complete collection of the writings of Culpeper and a fine copy of the book *De Contagione*, by Fracastorius (1546)—a rare volume. The gem of the collection is considered to be a copy of the first printed edition of Celsus, *De Re Medica* (1478). The Chalmers Library at the Royal Society of Medicine was formally opened on June 23rd, when Mrs. Chalmers was warmly thanked for her magnificent gift.

CONGRESS OF THE HISTORY OF MEDICINE.

THE Third International Congress of the History of Medicine will meet, as already announced, at the Royal Society of Medicine from July 17th to 22nd. It will be opened by Sir Alfred Mould, the Minister of Health, at 10.30 a.m. on the first day, when the delegates will be received, and Dr. Charles Singer, the President, will give an address. Academic dress will on this occasion be optional. The sessions will take place on the morning and afternoon of each day. The subjects chosen for general discussion are: The History of Anatomy, Veterinary as well as Human, and the History of Epidemiology from the Fourteenth Century. A large number of papers have been promised upon various topics of historical interest. The members will be received at the Royal College of Physicians on Monday afternoon; at the Mansion House by the Lord Mayor and Lady Mayoress on Tuesday afternoon; and at the Royal College of Surgeons by Sir Anthony Bowlby on Wednesday afternoon. Visits will also be made to the Barbers' Hall and to the Apothecaries' Hall, as well as to St. Bartholomew's Hospital. The congress will conclude with a banquet at the Hotel Cecil on Friday evening. Saturday will be devoted to an excursion to Windsor, and from thence by boat to Cookham, that the foreign visitors may see something of the beauty of the Thames in summer. The Wellcome Historical Museum will not only be open to members of the congress throughout the week, but Mr. Henry S. Wellcome issues an invitation to a conversazione on Wednesday evening. Those who desire to become members should communicate with Dr. J. D. Rolleston, the general secretary, 21, Alexandra Mansions, King's Road, Chelsea, S.W. The subscription is £1 12s. for members of the medical, dental, and veterinary professions, and 8s. for their wives, daughters, and sons as associates.

SOUTH AFRICAN MEDICAL CONGRESS.

THE eighteenth South African Medical Congress will be held, at the invitation of the Witwatersrand Branch of the British Medical Association, in Johannesburg, from September 18th to 23rd, with Dr. Charles Porter as president. The work of the Congress will be divided into five main sections, the names of which, with their secretaries, are as follows: Medicine, Dr. L. G. Irvine; Surgery, Dr. I. W. Brebner; Obstetrics and Gynaecology, Dr. R. W. B. Gibson; Public Health, Dr. A. Milne; Special Subjects, Dr. H. Gluckman; the address of all the secretaries is Johannesburg. The Congress will meet as a whole every morning to hear and discuss a paper on some subject of general interest. On the Monday of the Congress week the subject will be chronic rheumatism, introduced by Dr. Hugh Smith of Capetown;

on Tuesday a discussion on gastric ulcer will be opened by Dr. P. N. Vellacott of Bloemfontein; on Wednesday the subject of sterility will be introduced by Dr. E. R. Snijman of Kroonstad; on Thursday Dr. Park Ross of Durban will open a discussion on malaria; and on Friday the subject will be injuries and common diseases of the eye in general practice, introduced by Dr. Wood of Capetown. The sections will meet between 11 a.m. and 1 p.m., and each section will meet on two days; the early afternoons will be devoted to demonstrations. A programme of entertainments is being prepared. Every registered medical practitioner in South Africa is eligible for membership of the Congress, the subscription of visiting members being two guineas. Members wishing to read papers should communicate with the secretaries of the sections concerned at an early date. Further particulars may be obtained from the honorary general secretary of the Congress, Dr. Joseph J. Leviu, 5, Anstey's Buildings, Kerk Street, Johannesburg.

A NEW MEDICAL QUARTERLY.

UNDER the title of *Medicine* there has just been published the first number of an analytical review of general medicine, neurology, and pediatrics, edited by Dr. David L. Edsall of Harvard and Dr. John Howland of Johns Hopkins Medical School. Such a publication as this gives a more adequate means than is possessed by journals addressed to a wider medical public to discuss at full length subjects that help to a better comprehension of disease processes. In the different fields of medical science there is no lack of periodical literature of authoritative standing, but the editors entertain the opinion that so far there has been no attempt at comprehensive reviews in the field of clinical medicine in the English language. It is the aim of their periodical to provide such reviews, not only of internal medicine but of subjects in the border zone between medicine and surgery. In the first number there are only two articles: Dr. G. Canby Robinson contributes an essay on the therapeutic use of digitalis; from the fact that it fills 137 large octavo pages an estimate may be formed of the fullness with which the subject is treated. Dr. Robinson discusses the potency of digitalis, its effects on animals, the newer methods of its clinical study, its toxic and therapeutic effects, its use in heart failure and infectious diseases, and its dosage and preparations. He winds up with a copious list of references filling seven pages. The other article is on the treatment of meningococcus meningitis; it is written by Dr. Kenneth D. Blackfan, of Johns Hopkins Hospital, who, in some 67 pages, treats of the meningococcus and its strains, the preparation of an antimeningococcus serum, the diagnosis of meningitis, prophylactic measures, and treatment. The new periodical is well printed, and is published by Messrs. Williams and Wilkins, of Baltimore, U.S.A.; it will be issued quarterly. It is intended to publish in 1922 one volume of approximately 500 pages, and the subscription price is, for foreign countries, five and a half dollars.

RADIOLOGICAL SECTION AT GLASGOW.

The Section of Radiology and Electrolgy at the Ninetieth Annual Meeting of the British Medical Association at Glasgow will meet on Wednesday and Thursday, July 26th and 27th. The programme was published in last week's SUPPLEMENT (p. 251). Members who wish to take part in the discussion in this Section or to show skiagrams, etc., are asked to communicate at once with one or other of the honorary secretaries. The greatest care will be taken of all material, negatives, and prints, which should be sent to the local secretary (Dr. D. O. MacGregor, Langside Cottage, Glasgow) as early as possible, to allow of suitable arrangements being made for their exhibition.

"JOURNAL OF SCIENTIFIC INSTRUMENTS."

SOME six weeks ago we called attention to the project, fathered by the Institute of Physics after consultation with the Advisory Council for Scientific and Industrial Research and the Director of the National Physical Laboratory, for the

foundation of the *Journal of Scientific Instruments*. We pointed out that there was a distinct need for such a journal; the designing of scientific instruments is both a science and a trade, and the demand for instruments of precision can only be met by the co-operation of the experimenter and the instrument maker. Both need trustworthy information as to what is being done by others. These needs the proposed journal would meet, and a preliminary number was issued to a large number of persons interested in scientific pursuits, who were invited to fill in a form undertaking to subscribe for the journal. The Institute of Physics asks us to invite all those who intend to subscribe to communicate with the Institute without delay, so that an estimate may be formed of the support which may be relied upon. Unless sufficient support be forthcoming it will be impossible to start the journal. The subscription price will be 30s. a year, post free. Communications should be addressed to the Secretary of the Institute of Physics, 10, Essex Street, Strand, W.C.2.

As already announced, the annual dinner of the Royal Society of Medicine will be held at the Hotel Victoria, Northumberland Avenue, on Thursday, July 6th, at 7.30 for 8 p.m. It will be the first annual dinner of the society since the war began. Among the guests who have already accepted the invitation of the President, Sir John Bland-Sutton, who will be in the chair, are the Minister of Health (Sir Alfred Mond), Lord Riddell, the Presidents of the Royal Colleges of Physicians and Surgeons of England, the Regius Professor of Medicine in the University of Oxford (Sir Archibald Garrod), and the presidents of the principal medical societies. Fellows are invited to bring guests. The charge is 12s. 6d. each, exclusive of wine, and the diners, if they send their names in advance to the Secretary of the Society, 1, Wimpole Street, W.1, can change at the hotel free of charge.

THE Simon lecture of the University of London will be delivered by Professor H. S. Birkett, Dean of the Faculty of Medicine, McGill University, Montreal, at the rooms of the Royal Society of Medicine, 1, Wimpole Street, W.1, on Wednesday, July 12th; the subject selected is "The development of transatlantic rhino-laryngology." Admission is free without ticket. The chair will be taken by the Vice-Chancellor of the University, Mr. H. J. Waring, M.S., at 5 p.m.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Incipient Insanity: Proposed Government Bill.

IT is understood that Sir Alfred Mond, as responsible for the Board of Control, has under consideration the draft of a bill to enable persons suffering from incipient mental disease to be treated in public or private mental hospitals without certification. As the result of some informal conferences, the Minister hopes that something like an agreed measure may be presented and in such short compass as to secure prompt passage. The proposal follows upon a pledge given by the inclusion of a clause to deal with this matter in the ill-fated Miscellaneous Bill which Dr. Addison submitted in September, 1920. All the various provisions of that bill had to be sacrificed, but the importance of this subject has grown rather than diminished in the interval. It remains to be seen exactly what is contemplated. Broadly, the idea is that while the rich have resources available for curative care and attention, the poor have not, and that to afford facilities should prove economical in the long run, while avoiding for many the stigma of insanity and so inviting a freer use of existing facilities for treatment. It is pointed out that 35 per cent. of the certified patients in asylums are discharged in the course of time as recovered, and this is held to encourage the institution of methods for dealing with such trouble at an early stage if the patient is willing to take advantage of the opportunity. If the project meets with support county councils might, under improved financial conditions, be willing to provide separate homes or annexes for such sufferers.

National Insurance Bill.

At the sitting of Grand Committee on the National Health Insurance Bill on June 27th, a compromise was reached on the financial matter upon which the Government was defeated at the previous sitting on June 22nd. Under the bill the Government proposed to transfer from the Treasury to the benefit funds of the approved societies the cost of the further provision made some time ago in respect of medical benefit. This was to have been done on the suggestion of the Advisory Council, as a better arrangement, until December 31st, 1923, than raising the amount of contributions. Mr. Cantley, however, carried at the sitting on June 22nd, by 20 votes to 14, an amendment to transfer the cost from the Treasury to the central fund. Sir Alfred Mond, at the sitting on June 27th, proposed that about £300,000, or a little less than one-third of the amount involved, should be drawn from the central fund and the rest from the benefit funds. The Committee stage of the bill was finished.

Territorial Army: Medical Appointments.

Lieut.-Colonel Fremantle asked, on June 21st, what compensation was proposed for those D.A.Ds.M.S. of the Territorial Army whose appointments, made for a period of four years, had been terminated at the expiration of two years or less. Sir R. Sanders replied that those Deputy Assistant Directors of Medical Service whose appointments, originally made for a period of four years, had been prematurely terminated from March 1st last, would be given as compensation a sum representing one-third of what they would have received in pay and allowances if allowed to complete the term of their appointment.

Milk and Dairies Amendment Bill.

The Earl of Onslow, on June 20th, introduced in the Upper House the Milk and Dairies Amendment Bill, which was read a first time. The second reading of the bill was moved by Lord Onslow on June 26th.

Lord Onslow said that the Government would have preferred to allow the Act of 1915 to come into force as was provided by the Act passed in 1917. The reason why its operation was to be postponed—it was not to be scrapped—was that at present the country could not afford the cost that would be involved. The Act of 1915 would place new duties on the county councils. An interdepartmental committee, which sat in 1920, estimated that the cost would be £700,000 a year. The Ministry of Health, which went into the matter separately, put the cost at not much less. In addition the amount of money necessary for the payment of compensation on account of tuberculosis was estimated at £150,000 a year. As time went on the expenditure would increase until the end of about three years, when it would begin to decline. Legislation was necessary, as otherwise the Act of 1915 would operate next September. Moreover, two orders of the Food Ministry as to the grading of milk and for the prevention of adulteration would expire in September. The present bill sought to do three things: (1) To prevent milk being sold which was contrary to the interests of public health; (2) to provide milk at a cheap rate, and plenty of it, from herds which were inspected and free from bacteriological contamination; and (3) to prevent the sale of milk from cows suffering from tuberculosis of the udder. Clause I would give power to local authorities to remove a retailer from the register if it appeared in the interest of public health; but he would have right of appeal to a court of summary jurisdiction, and of further appeal to quarter session. Clause II would provide for three designations of milk—namely, "Certified," Grade A, and Pasteurized. The definitions would be made by orders after consultations with parties concerned. Clause IV would deal with colouring matter, and Clause V would prohibit the sale of milk from a cow suffering from tuberculosis of the udder. If the milk was sold knowingly there would be liability to a fine of £100 or imprisonment for six months. Clause VII would deal with the regulations to be made by the Ministry of Health in regard to the importation of milk. The bill would apply to Scotland.

Lord Strachie, on behalf of several agricultural bodies, opposed the measure on the ground that this Act of 1915 should be brought into operation; he submitted that the large expenditure talked of as required under that Act would not be necessary. Local authorities objected very much to "roving commissions." When prosecutions were contemplated from distant towns the first step by those intending to take action should be to communicate with the medical officers of the county areas.

Viscount Astor and the Marquess of Lincolnshire supported the bill, and it was read a second time, Lord Strachie not pressing his objection at this stage.

Local Government Officers' Superannuation.—The Local Government and Other Officers' Superannuation Bill (a private measure), as amended in Standing Committee, was considered in the Commons on June 23rd. On Clause 2 Sir A. Mond moved an amendment to provide that no superannuation scheme should be introduced by a local authority unless there were a majority of not less than two-thirds of the members of the council present and voting. On Clause 4, at the instance of Sir A. Mond, a paragraph was omitted which would have excluded from the proposed benefits under the bill an officer or servant of a local authority getting pension or superannuation right under a public general Act of

Parliament—that is to say, for another office. Another amendment was moved by Sir A. Mond to define "service" in such a way as to enable officers to transfer from one local authority to another without loss of superannuation rights. An amendment by Sir R. Bainsby to confine the operation of the bill to whole-time service was rejected. Sir A. Mond said the reason for including half-time officers was that there were people like medical officers of health, who in many cases were not whole-time officers, but who did come within superannuation schemes now, and it would be unfair to exclude them from benefits. On Clause 5—to permit combinations of local authorities—Sir A. Mond moved an amendment to allow combination where the areas of two or more councils were situated wholly or partly within one county. The clause would have made it necessary that the two areas should be entirely in one county.

Lunacy Visiting Committees Bill.—Sir Robert Newman, on June 21st, obtained leave to bring in a bill to enable local authorities to co-opt members of visiting committees, and to provide for the appointment of women as members of visiting committees. He explained that the object was to enable county councils and other local authorities thus to add a certain number of persons from outside their bodies to serve on their visiting committees. He referred to the precedent afforded by the powers given to county councils in regard to education committees and to limited powers of co-optation possessed by boards of guardians. There were no fewer than 50 per cent. of the county councils which had no women members, and in less than 50 per cent. no woman had been appointed on the asylum visiting committees. Considering that the majority of the inmates were women, it seemed to him regrettable that in so many cases no woman should be serving on committees. There was a provision in the Act of 1913, enabling local authorities to appoint women, but this was conditional on their appointing their visiting committees to asylums as committees to deal with the care of the mentally defective. Councils often rather objected to reconstructing their committees to enable some woman to be appointed. The bill was backed by Mrs. Witheringham, Lieut.-Colonel Hurst, and Dr. Fremantle.

The Care of the Insane.—The Board of Control some little time since, acting with the concurrence of the Ministry of Health, appointed a committee which is now considering in what way the nursing service in mental hospitals can be improved. The Board has also appointed a committee to consider the dietary of these institutions and to report whether any improvements can be effected.

Sir George Newman's Salary.—Sir J. Leigh asked, on June 21st, on what grounds the salary of Sir George Newman, Chief Medical Officer to the Ministry of Education, had recently been advanced to £2,500 a year. Sir A. Mond said that under an arrangement made when the Ministry of Health was founded, and very much to the benefit of the public service, Sir George Newman performed the duties pertaining to the post of Chief Medical Officer of the Ministry of Health and Chief Medical Officer of the Board of Education. Before the posts were combined the salaries were £1,800 for the Principal Medical Officer of the Local Government Board and £1,500 for the Principal Medical Officer of the Board of Education, making a total of £3,300. It would be seen that under the present arrangement the cost to the Exchequer had been substantially reduced. The appointment was whole-time. The Medical Department of the Ministry of Health and the Board of Education were controlled by the Permanent Secretaries of those departments under the respective Ministers. Sir George Newman had the status of a Secretary in the Ministry of Health, and his salary was raised from £2,100 to £2,500 as part of the arrangements made for the whole service by the Treasury arising out of the report of the committee presided over by Mr. Asquith. Sir H. Craik asked whether this salary was not £500 in excess of the salary of the President of the Board of Education. Sir A. Mond said the comparison should be made with his own salary as an official subordinate to him. Colonel Ashley wished to know how the increase of £500 was justified in view of the statement that the country could not afford the present cost of education. Dr. Murray wondered whether it was observed that it was millionaires in the House who asked the questions about the salaries of men who had done great services for their country.

Insurance Practitioners and Urgent Cases.—Sir John Leigh inquired, on June 21st, whether it was the practice of panel doctors in certain parts of London to lock up their surgeries after a certain hour and depart to other districts, and thus to be inaccessible to patients requiring immediate attention. Sir A. Mond said his attention had been called to certain cases of this kind, and he was having further inquiries made. Such practice could not be regarded as complying with the terms of service of insurance practitioners.

Pensions Hospitals.—In answer to Sir J. Leigh, on June 22nd, Mr. Macpherson said that the number of Pensions Ministry Hospitals was fifty-two. Seventeen hospitals had been closed during the past twelve months and it was proposed shortly to close two others. The number of in-patients on June 3rd was approximately 10,000. On the same date in 1921 and 1920 the numbers were 11,700 and 7,650 respectively.

Medical Referees.—In a written reply to Sir H. Nield, on June 15th, Mr. Shortt stated that about eighteen months ago he considered the remuneration of medical referees appointed under the Workmen's Compensation Act (which Sir H. Nield stated stands at pre-war terms), but he concluded there were not sufficient grounds for asking the Treasury to make a revision. He appreciated the valuable and important services rendered, but having regard to all the circumstances, including the general financial situation, he did not think that an increased scale with its consequent addition to public expenditure could be justified.

Efficient Vaccination.—Dr. McDonald asked, on June 21st, if, in view of the increasing practice of many medical men to certify successful vaccination on the production of one vesicle with commercial lymph, the Minister of Health would authorize public vaccinators to use their discretion, in cases of objection to four marks, to insert a smaller number, but not fewer than two, in order that a larger number of children might become protected by the more effective and purer lymph supplied by the National Vaccine Establishment. Sir A. Mond regretted he could not do as suggested. It was essential that vaccination performed at the public expense should be maintained at a high level of efficiency. He was advised that the number, area, and character of the vaccination marks had an important bearing upon the degree and permanence of the protection afforded by vaccinations against small-pox.

Medical Uses of Cocaine.—Dr. McDonald asked, on June 21st, if the Minister of Health was aware that cocaine was not a drug which was essential to the medical and dental professions, inasmuch as many less toxic substitutes were manufactured. Sir James Baird (Under Secretary for the Home Office), replying, said that this department was in consultation with the Ministry of Health as to the need of cocaine in medical and dental practice, and he was not prepared at present to express any opinion on the suggestion that its importation should be entirely prohibited.

The Statistics of Cancer.—In reply to Mr. R. Young the Minister of Health said that he was fully aware of the importance of investigating the causes of cancer by all possible means, but there were insuperable difficulties in drawing accurate inferences from comparison of recorded cancer death rates in the different countries of the world. The question of international study of cancer prevalent was, however, receiving attention in the department, and was being brought before the international bodies concerned with public health questions.

The Feeding of Destitute Families.—Dr. Fremantle asked, on June 21st, if the Minister of Health was aware that the procedure whereby destitute families received relief in money and in kind from three separate authorities—namely, boards of guardians, education authorities, and borough or urban or rural district councils—commonly resulted in an uneconomic and defective dietary; and whether he proposed to take any steps to centralize the organizations concerned with a view to a better physiological use of the resources available. Sir A. Mond said he knew that in certain circumstances assistance might be given to destitute families from the three sources mentioned. Steps were being taken, as far as practicable, to prevent overlapping.

The Supply of Radium.—Sir E. Nicholl asked, on June 26th, whether, having regard to the uses of radium for medical purposes, the Minister of Health was making inquiries with the object of obtaining this hitherto scarce substance, and whether he knew that considerable quantities were to be found in England, notably in Cornwall, but largely undeveloped. Sir A. Mond said that the Medical Research Council had a provisional supply of radium at its disposal. An increasing demand was to be expected, but he was not in a position to recommend the development of its production in any particular area, as that obviously depended upon geological and commercial considerations.

Blind and Deaf Children.—Mr. Fisher, answering Mr. Stanton, on June 22nd, stated that notwithstanding the present financial difficulties, it will be possible to allow existing schools for the education of blind and deaf children to be used to the full extent of their accommodation.

Infanticide Bill.—This measure, originally called the Child Murder Bill, was read a third time in the House of Lords on June 27th.

Dogs Act Amendment Bill.—Colonel Barn, on June 26th, introduced a bill to amend the Dogs Act, 1906. It was backed by Mr. Joseph Green and Sir Frederick Banbury, and was read a first time.

Pension Appeal Resources.—On a suggestion by Major Kelley that specialists should be asked to make special inquiry as to the pre-war health of ex-service men deprived of pensions, Major Tryon, on June 20th, explained the existing resources of such a man for appeals. Every man dissatisfied with the assessment of his disablement had a right of appeal either to a medical appeal board or to an assessment appeal tribunal, and every man who was refused pension on the ground that his disability was not due to service had a right of appeal to an entitlement appeal tribunal. In the case of a medical appeal board a specialist sat on the board, and in the other cases the tribunal was empowered to consult a specialist when it considered that course necessary. The man's complete medical history, so far as obtainable, was always placed before the board or tribunal.

Blind Persons Act.—Sir A. Mond has stated that thirty-two local authorities have not submitted schemes under the Blind Persons Act, 1920. All schemes submitted had been approved or promised approval subject to modifications. Twenty-seven authorities had schemes under consideration, and he trusted that the remaining authorities, five in number, would reconsider their decision in the matter at an early date.

The Case of Ronald True.—Mr. Holmes, on June 19th, asked what course was pursued in the case of a man who, having been found guilty of murder, sentenced to death, reprieved on the ground of insanity, and ordered to be detained as a criminal lunatic, was subsequently certified as having recovered his sanity? Mr. Shortt replied that the Criminal Lunatics Act of 1854 provided that where a man was certified sane in the circumstances mentioned, the Home Secretary, if satisfied that it was proper to do so, might direct that he be remitted to prison to be dealt with according to the law.

THE PLIGHT OF RUSSIAN DOCTORS.

As recorded in last week's SUPPLEMENT the Council of the British Medical Association on June 14th considered a letter from the Russian Committee for Famine Relief, giving the substance of an appeal from the Pirogoff Medical Society for help for starving medical men and their families in Russia. During the course of discussion the Treasurer and other members of the Council urged that the quickest and most certain way of obtaining support would be by direct appeal from the head office to each member. It was unanimously resolved that an appeal should be issued to members on behalf of the fund, that the subscription asked for be 5s. a head, and that secretaries of Branches and Divisions be asked to give all assistance in their power. In accordance with this decision a letter is now being circulated to all members of the British Medical Association in Great Britain and Ireland. Needless to say, contributions from other members of the medical profession would be welcomed. Further reference to the appeal is made elsewhere in a leading article. The Association's letter is as follows:

AN URGENT APPEAL TO THE BRITISH PROFESSION.

British Medical Association,
429, Strand, London, W.C.2.

DEAR SIR OR MADAM,

The Council of the Association at its meeting on June 14th received a most pathetic and pressing appeal for help to the starving medical men and their families in various parts of Russia. The communications we have had with Russian medical men in this country and from the Russian Committee for Famine Relief, make it clear that the Russian medical societies have done their best to help their own colleagues so long as that was possible, but now they feel compelled to appeal to their brethren in other parts of the world. The conditions are truly appalling, as the Russian medical profession is to a great extent literally starving and losing a very large number of its members in the fight against epidemics of every kind.

The appeal is for the only form of assistance which under the circumstances can be effective—namely, food parcels sent to individual medical men, and to groups for distribution among members in greatest need. Lists have been given to us of doctors and families of deceased doctors to whom food parcels must be sent without delay if they are to be saved from actual starvation. The method of sending these food parcels is through the American Relief Administration, 67, Eaton Square, S.W.1, which makes itself responsible for the delivery of the parcel to the individuals addressed, and gets a receipt from them showing that the parcel has actually been received. The contents of each parcel have been decided upon, after much experience, by the American Relief Association. Each parcel costs £2 4s., inclusive of all charges.

The Council, on hearing these and other particulars, came unanimously to the conclusion that this was a case for prompt action and an appeal to which every medical man ought gladly to respond. The Council desires not only to send relief to our starving colleagues, but to show them that the response has been immediate and widespread, and for that purpose it has resolved to limit the subscription to 5s. and to ask every one of the members of the Association to subscribe that sum and to send in the enclosed addressed envelope a postal order or cheque at once, payable to Mr. L. Ferris-Scott, the Financial Secretary of the Association, who will send a receipt. Subscriptions were immediately received from each member of the Council present on June 14th.

It will not be possible to acknowledge all the names of subscribers in the BRITISH MEDICAL JOURNAL, but the amount of money collected each week will be notified there. The money received will be promptly used in the dispatch of food parcels to Russian doctors and their families through the American Relief Administration. It is most earnestly hoped that the response will be commensurate with the desperate need of those for whom this appeal is made.

Yours faithfully,

DAVID DRUMMOND,
President.

R. WALLACE HENRY,
Chairman of Representative Meetings.

ROBT. A. BOLAM,
Chairman of Council.

G. E. HASLIP,
Treasurer.

June, 1922.

EPSOM COLLEGE.

The annual general meeting of the governors of Epsom College was held at 49, Bedford Square, London, on June 23rd, with Sir HENRY MORRIS, treasurer, in the chair. The names of successful candidates for foundation scholarships were announced as follows: Ian C. L. Watson, Robert C. Rees, John E. Stevenson, John C. Edwards, William J. Downer, and Frank J. Griffin. The successful candidates for pensionerships were Evelyn O. Cox, Catherine A. Kindou, and Louise B. Shells. The annual report states that the Rev. Walter J. Barton, who had held the office of headmaster of the school since 1914, had resigned, his resignation taking effect from the end of the Lent term, and that Mr. Arnold C. Powell, headmaster of Bedford Modern School, had been appointed in his place. Since the last annual meeting three boys had passed the first examination for medical degrees of the University of London, as well as one in chemistry and physics; and one in chemistry and biology; one boy had passed the first examination for medical degrees of the University of Cambridge.

In submitting the report of the council to the governors Sir HENRY MORRIS drew attention to the fact that owing to the small margin of profit on the income and expenditure account for the past year, and in view of the new scheme of superannuation allowances which had come into operation on January 1st last, the council had decided that the school fees of all boys entering the College after the summer term, 1922, should be raised as follows: Sons of medical men from 100 guineas to £120; lay boys from 120 guineas to £140; day boys £40 to £45. The applications received for the mortgage debenture bonds of £100 each at 5 per cent. interest on the security of the College land and buildings amounted to £24,000, so that there were only eight more debenture bonds to be allotted. He expressed the cordial thanks of the council to those friends who had responded to their application to help the College at a critical time. The council would, it was hoped, very shortly be able to put in hand the rebuilding of the nave of the chapel in harmony with the new chapel, as the cost of building had been materially reduced. He mentioned that the joint total of the War Memorial Fund and of the Chapel Building Fund available for this purpose was over £6,300.

Colonel J. Paul Bush, C.M.G., a member of the council and honorary local secretary for Bristol, was elected a vice-president of the College. At the close of the business a cordial vote of thanks was proposed by Mr. ERNEST PAGE, K.C., the chairman of the council, to Sir Henry Morris for the great service rendered by him to the College as treasurer; this was seconded by Sir WILLIAM CHURCH, and carried by acclamation.

England and Wales.

WATER SUPPLY IN A DRY SUMMER.

THE Ministry of Health issued last week to medical officers of health a memorandum on "conserving and supplementing existing supplies of water." Under the first head advice is given with regard to the prevention of waste, and it is suggested that water authorities should offer to replace, free of charge, defective washers to taps. It is extremely odd that this suggestion should have to be made, since it is the duty of the water authority to give an adequate supply, which obviously places upon the authority the duty of preventing waste. Suggestions with regard to restrictions of ordinary consumption are prefaced by the statement that an average domestic consumption of sixteen gallons a head a day is generally quite adequate in most towns under present conditions, whereas the consumption is in many places twice or three or more times this amount with no commensurate gain and much waste of pumping power, which means not only a risk of shortage in some seasons, but a constant waste of money. Various suggestions are made with regard to trade and compensation water. In the second part of the memorandum the water authorities are advised to consider the possibility of pooling their resources and are instructed when contemplating additional sources of supply to consult their medical officer of health with regard to water for domestic use. Finally the Ministry offers to help local and water authorities in carrying out the measures suggested. This offer was originally made in a circular letter dated March

29th, 1922; advice was then also given with regard to the measures which should this year be taken in consequence of the depletion of water supplies resulting from the prolonged drought of last year. Medical officers of health have also been supplied with copies of a circular letter issued last September on chlorination, and the methods of applying it are described in an appendix. All these documents are accompanied by a covering letter from Sir George Newman, chief medical officer to the Ministry, in which, among other things, the attention of county and district medical officers of health is called to the importance of public health questions arising out of shortage of water as it affects areas under their charge, including rural areas, and to the rural in character and do not.

Where this has not been done should be made as to the present condition of water supplies in any district in which the medical officer of health has reason to believe that material shortage of water exists or is likely to occur; he should advise his authority on the nature of the measures requisite for safeguarding the use of additional and unusual sources of supply, on the precautions which should be adopted if public services have to be interrupted, and on the public health considerations which should govern the selection of other special measures that may be proposed to prevent the waste of water.

MANCHESTER CHAIRS.

Mr. E. D. Telford, M.A., B.Ch.Cantab., F.R.C.S.Eng., has been appointed to the Chair of Systematic Surgery in the University of Manchester in succession to Professor J. W. Smith, who will vacate the chair in September. Mr. Telford is honorary surgeon to the Royal Infirmary and lecturer in surgery at the University. Mr. William W. C. Topley, M.A., M.D.Cantab., F.R.C.P.Lond., has been appointed professor of bacteriology in the University and director of the Public Health Laboratory. Dr. Topley at present holds the position of director of the Institute of Pathology and lecturer in bacteriology and pathology at Charing Cross Hospital, London, and was formerly demonstrator of morbid anatomy and assistant director of pathology at St. Thomas's Hospital. He was bacteriologist with the R.A.M.C. Mission that went to Serbia in 1915.

LIVERPOOL CHAIRS.

The Council of the University of Liverpool has nominated Professor F. R. Glynn to be emeritus professor of medicine, and Professor W. Thelwall-Thomas to be emeritus professor of surgery. It has appointed Dr. John Hill Abram to be professor of medicine. He was one of the first students of University College, which originated in the Liverpool Royal Infirmary School of Medicine. Dr. Abram is senior physician to the Royal Infirmary and President of the Liverpool Medical Institution. During the war he was in charge of the military and naval beds at the Royal Infirmary and his medical services were in constant demand for the local temporary hospitals during that period. Professor W. Thelwall-Thomas is succeeded by Mr. Robert Ernest Kelly, who was a Liverpool student; he graduated B.Sc. in the Victoria University of Manchester in 1899, and M.B., B.Ch. in the University of Liverpool in 1901. He took the M.D. degree in 1905 and became F.R.C.S.Eng. in the same year. He is honorary surgeon to the Liverpool Royal Infirmary. He served in the R.A.M.C. during the war, and in 1917-18 was consulting surgeon, with the rank of colonel, to the British Salonica Force. Jointly with Sir Crisp English he described his experiences with that force in our columns of March 16th, 1918. For his services during the war he received the C.B. in 1919.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

Sir George Makins, G.C.M.G., consulting surgeon to the hospital, presented the prizes at St. Thomas's Hospital Medical School on June 22nd. The chairman (Sir Arthur Stanley, treasurer of the hospital) expressed regret at the absence of the Duke of Connaught, president of the hospital, which was due to the fact that he had gone to welcome home the Prince of Wales from his world tour. Sir Cuthbert Wallace, dean of the school, referred to the progress of the school. A very serious difficulty would, he said, arise if the financial position of voluntary hospitals caused them to be closed, and with them the medical schools. It was of the utmost importance that the voluntary hospital system should be kept alive. Unfortunately three wards in St. Thomas's had had to be closed for want of funds, and it was very urgent

that they should be reopened. After presenting the prizes Sir George Makins, in addressing the students, impressed upon them their responsibilities towards the school, and said that it was for them to justify the trust reposed in them.

Ireland.

MEDICAL BENEVOLENT FUND.

THE annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held at the Royal College of Surgeons, Sir Wm. Wheeler presiding. During the past eighty years the Central Committee of the Royal Medical Benevolent Fund Society has worked for the benefit of members of the Irish medical profession in distress. The report of the society was read by Sir John Moore at the annual meeting. The committee points out that the society is a purely Irish one, and that its funds are allocated only to deserving cases arising in Ireland. It is, the committee says, a positive disgrace to the medical profession that three out of every four of their colleagues have no thought for their brethren in distress. Most of the donations and grants given from year to year were granted to widows and orphans of men who had never even contributed one penny. Last year the applicants numbered 72, the amount of the grants being £1,215 11s. The society's revenue for the year was £1,929 15s. 5d., as compared with £1,675 9s. 1d. the previous year, which was a record. The balance in the bank at the end of April was £1,200 12s. 2d. Dr. Ashe agreed as to the need for more support. On his motion, Dr. Croly seconded, the report was adopted. On the motion of Dr. Kirkpatrick, seconded by Mr. Blaney, a resolution was passed urging on members of the profession the importance of sending even a small annual contribution to the fund. The committee were empowered to give grants in deserving cases to orphans of medical practitioners. Sir James Craig, who took the second chair, pointed out that they know nothing of politics or religion, and that the legacy of £2,000 from the late Mr. Musgrave, Belfast, was available for all Ireland.

Correspondence.

THE PROFESSION AND THE POLICE.

SIR,—I have lately ascertained that there is in this country an arrangement between the General Medical Council and the Home Office under which the "convictions of registered medical and dental practitioners are all reported to the Council and are duly recorded, including what may be regarded as trivial offences, such as those under the Motor-Car Acts, or those of which you speak" (a stray puppy). So that it is a fact that if during a doctor's round his chimney is fired and he is fined he is reported to the Council and his offence is "duly recorded"! This is not embroidery of mine. My little girl's puppy dog infringed a county by-law. I was summoned. The superintendent told the magistrates' clerk that if I were fined I must be reported to the Council. The clerk handed this information to the Bench, and they in consequence refused to convict and dismissed the case on payment of costs. (Oh, shade of W. S. Gilbert!)

I wish now to offer criticism, destructive and constructive, of this system; emphatically of the system, not of the Council itself. I speak as a practical magistrate of experience. I condemn absolutely the secrecy of this arrangement, savouring of the espionage of the dossier system. Medical men are entitled to know the rules of the game. No one to whom I have spoken is aware of this secret system. It should be made known to magistrates; their convictions are often modified by ulterior consequences—loss of pension, or employment, or some professional indignity, as in my case quoted above.

Then I am not satisfied that trivial offences are under the jurisdiction of the General Medical Council. Sec. 29, Medical Act, 1858, reads:

"If any medical practitioner shall be convicted in England or Ireland of any felony or misdemeanour or in Scotland of any crime or offence, or shall, after due inquiry, be judged by the General Council to have been guilty of infamous conduct in any professional respect, the General Council may, if they see fit, direct the Registrar to erase the name of such medical practitioner from the Register."

I submit that only actions which *prima facie* might subject the offender to the penalty of being struck off the Register are here included. That this was the intention of the framers of the Act in 1858 is evidenced by the fact that for nearly fifty years after only felonies were reported. Then in 1906 a indictable offences (tried by jury) were reported, and in 1911 all offences, however trifling. Is not this a good example of real bureaucratic government and departmental encroachment? I hold no brief for any black sheep in my profession and if it be established that the General Medical Council has jurisdiction over the whole flock, from the blackest sheep to the lamb with a soupçon of grey in his fleece, then someone must diagnose the degree of blackness. I offer the following solution as one dealing adequately with real offenders, without subjecting anyone to indignity or injustice.

1. Convictions for indictable offences. These are provided for in the present system. They are reported (a) by prison governors in cases of commitment to prison; (b) by metropolitan police in London, where fine is imposed; (c) by chief constables in the country.

2. Convictions in courts of summary jurisdiction, before magistrates without jury. These cases are at present all reported to, and dealt with by, the Penal Cases Committee of the General Medical Council. In all English tribunals the evidence on both sides is heard; all details which aggravate or extenuate are before the judges of the case. This would necessitate a member of the Penal Cases Committee sitting with the magistrates in every case in which a doctor was tried, and retiring with them to consider the evidence. A conviction does not tell the whole tale; there are grades of guilt and grades of conviction. I assume that in the first instance only the fact of the conviction is now reported by the police. Any subsequent or additional information is supplied by them. This is wrong. Their information is at best *ex parte*; they are in no sense a judicial body; they are often the prosecutors. The chief constable takes no notes of evidence given; he does not enter the magistrates' room, where evidence is sifted. He can only furnish the fact of a previous conviction (if any); other details are a matter of his memory. I give two practical cases within my own knowledge: A medical man when drunk struck his wife—conviction for assault. Another medical man struck his wife who was drunk—conviction for assault. It would require a *Sherlock Holmes* to spot which was the bad and which the martyr from simple police reports of these two cases. Even in "drunks" there are degrees of guilt. If my son (now first year) were just qualified and celebrated the occasion "too well" and were fined, I should like him reprimanded by a magistrate and not classed in the records of the General Medical Council with a man drunk when in professional attendance. The solution I advocate is practical—namely, co-operation between the Council and the magistrates. The men appointed by the Crown to administer justice on oath are the only ones qualified in their judicial capacity to assess for the Council the gravity of their convictions. They would spare the doctor who struck his wife under the great provocation of her drunken habits the extra penalty—rather cruel—of being reported to the Council. It is, to my mind, unthinkable that the Council should fear lest magistrates would shield real culprits. A word from the Home Office would secure that all serious medical offenders would be duly reported to the General Medical Council by the convicting Bench through their justices' clerk. This arrangement would scrap for ever the reporting and recording of trivial offences—a consummation devoutly to be wished, in my opinion.

I trust that the Council will regard my criticism as written without malice in the best interests of my profession.—I am, etc.,

Stockport, June 26th.

J. M. BRENNAN.

INFLUENZA.

SIR,—Controversy with reviewers is not to be pursued, but since in your columns (June 24th, p. 999) a defender of the Ministry of Health's Report on Influenza charges me with (1) definite error, (2) grave misunderstanding, (3) inaccuracy and (I think) misrepresentation, I trust that you will allow me, in fairness to my collaborators, some opportunity of rebuttal.

1. It is true that in two footnotes to the Report *bibliographical* reference is made to papers by Dr. Hamer and by myself; but the fact remains that in the Report there is nothing to indicate what are the general and special ideas

put forward by us in respect of the theory of epidemic constitutions, and nothing to indicate to the reader that these ideas are under critical discussion in the Report. I do not see my "definite error," therefore.

2. It is suggested that I have gravely misunderstood certain passages of the Report. The footnote on page 17, the sentence, "But little in written history can be brought forward as foreboding an impending change in the years immediately before 1890," and a perusal of private letters, now before me, written by the author of the passages I have criticized, show that there has been no misunderstanding whatsoever. The thesis writ large on page 17 is that the pandemic of 1889 and later years was heralded by no "prodroma" of an epidemiological nature; and this is the thesis I have refuted. If I am wrong, the footnote on page 17 is irrelevant.

3. I am told that another instance of my inaccuracy is my characterization of certain observations in the Report as an official theory. The observations thus alluded to are, in the Report, thus prefaced:

"Our general theory of the epidemiology of influenza may now be enunciated";

and are thus dismissed:

"Such is the general theory of epidemiology which we are led to adopt as a working hypothesis."

When an official writer, in an official report, uses the royal and editorial style, enunciates a theory, and says that it is adopted as a working hypothesis, then that theory becomes "official," whatever disclaimer may be elsewhere made in respect of intention and exposition. It is an abuse of criticism to charge an essayist, who refers to such a theory as "official," with inaccuracy. When asked some time ago to review the Ministry of Health's Report in your columns I refused to do so on the ground that my criticisms would appear over my own name. They have done so, and I will gladly modify any expression which any person aggrieved may show to be unjustified. But there would be no profit in continuing discussion with an anonymous reviewer who, with so little justice, uses the "prætor's" words—"definite error, grave misunderstanding, and misrepresentation.—I am, etc.,

London, June 23rd.

F. G. CROOKSHANK.

SERUM BY THE MOUTH.

Sir,—In the review of *Hormone Therapy by Sera, Vaccines, and Drugs*, by Dr. D. Montgomerie Paton of Melbourne, you say his experience "with the oral administration of antidiptherial serum in various diseases" goes back for "twenty-three years." I venture to think that mine goes back for nearly thirty years, to 1892, and I have frequently spoken (as at the Edinburgh meeting) written frequently on the subject.

conclusions may be of interest:

The oral administration of serums and vaccines (such as antisthmatic) is better than the hypodermic. There is much less chance of anaphylaxis, and a small precautionary dose is much more readily given.

Absorption is readily effected. There is no pain, no puncturing of a vein, and no abscess, and one very striking benefit is the absence or modification of skin rashes.

I commenced giving serums by the mouth in 1892 from finding out the benefit of thyroid feeding, and my M.D. thesis was based on myxoedema treated in this way, and at the British Medical Association meeting in 1893, in Newcastle I showed a case treated with benefit by cooked thyroids, thus proving that the active principle is not destroyed by heat, and I am confident that the active principles of serums are not destroyed by digestion.

I regard anti-diphtheria serum as a specific in raising body resistance, not only in diphtheria, but in other severe diseases as well—notably in pneumonia and influenza. I think 5,000 units of this serum is more powerful in this way than 20,000 units of any other variety, such as antistreptococcal. Why I do not know, but it cannot be the horse serum *per se*.

Other advantages are that it can be dispensed with a little aqua chloroformi as a druggist, and a busy practitioner has not to return with, and inject, the serum.

Tuberculin is, I believe, altered or digested, and must be injected; but all other serums, and even vaccines, except, perhaps, that against small-pox, can, I think, be best administered orally.—I am, etc.,

T. M. ALLISON, M.D.,

Honorary Physician to the Wingrove Hospital,
Newcastle-upon-Tyne.

June 19th.

STERILIZATION OF MENTAL DEFECTIVES.

Sir,—Mr. T. Davies, M.P. for Cirencester, a well-known worker in the cause of education in Gloucestershire, recently made a second attempt to call public attention to the urgent necessity of taking effective steps to deal with the increase of mentally defective persons. As his speech in the House of Commons was very scantily reported in the lay press I wish to draw the attention of the profession to it.

He called attention to the case of Martin Kallikak, who had an illegitimate son by a mentally defective girl, in the American revolutionary war. In 1912 there were known to be 480 direct descendants of this union; 36 were illegitimate, 33 were sexually immoral, 24 were confirmed alcoholics, and 8 kept places of ill fame. The explanation of so much immorality is that of the 480 descendants 143 were known to be feeble minded, and many of the others were of questionable mentality. He also quoted the case of the Nam family. Briefly, of 784 descendants 658 were either alcoholics, liectious, or became prisoners. It was estimated that up to date these cases have cost the State one and a quarter million dollars. While fully realizing it is a strong measure to suggest, he pointed out that sterilization of both sexes is carried out with great benefit in fifteen States in America. In the county of Gloucester they have refused to take charge of mental defectives, though they have been told it is their duty under the Act, on account of the enormous expense. This means the defectives are living at home. He asked that a committee should be appointed to consider the question in view of the fact that these people have large families and increase rapidly.

I have been struck by the suffering of mental defectives with a criminal tendency. One man I knew, whose father was ultimately certified as insane, spent nearly twenty years in gaol. For many years he was a source of danger and contamination to the community. He finally induced another man, who had never committed crime before, to join in a robbery, which ended in violence and narrowly escaped being a murder. He was then sent to a criminal lunatic asylum.

Sterilization may inflict hardship on certain individuals, but such cases as this need to be put on the other side of the scales when the matter is being weighed. It is obvious that sterilization would only be one of the measures required, but it would be interesting and valuable to hear the views of those who have had experience of sterilization as to its effects on the health of individuals, as this is a matter of great importance and one on which the public would need to be satisfied before any such measure could pass into law.—I am, etc.,

A. E. J. LISTER, M.B., B.S. (Lond.), F.R.C.S.,
Lieutenant-Colonel (R.S. Retd.).

London, W., June 22nd.

THE INTERSTITIAL GLAND AND SEX PROBLEMS.

Sir,—Lecturers and teachers sometimes would have us accept as theory what never was other than assumption or surmise.

Did all that Rumley Dawson wrote so thoughtfully upon "Causation of sex" ever carry us beyond hypothesis? Is there any demonstration of fact of a genetic male (right) and female (left) ovary? One had thought this notion had been relegated to the lumber room of interesting but exploded myths! An unmarried patient of mine, suffering for years severely with dysmenorrhoea, developed appendicitis, for which we operated, removing an affected appendix and also the right ovary studded with small cysts. Recovery uneventful, and a complete freedom from symptoms. After a period of eighteen months marriage was followed by the birth of a vigorous male child.

Did a staid right ovarian ovum wait in patience all those months for fertilization?—I am, etc.,

Manchester, June 19th.

FREDERIC RAWLINGS.

THE NATURE AND SIGNIFICANCE OF HEART SYMPTOMS.

Sir,—Sir James Mackenzie's recent articles on the nature and significance of heart symptoms must have been read with pleasure and profit by most of the practising physicians in the British Empire, and it may be said that those who have neglected to make themselves acquainted with the results of his epoch-making researches are hopelessly behind the times. We have every reason to be proud of another fellow

countryman, who takes rank with Harvey in the elucidation of circulatory phenomena.

It is therefore with some diffidence, and with all due deference, that I venture to express my regret that in his article of April 15th Sir James Mackenzie perpetuates an error in dynamical terminology which has been universal among English writers on the heart, and among teachers, ever since my student days. I refer to his use of the terms "reserve force" and "rest force," where "power," not "force," is what is meant. A motor car may be using ten horse-power when travelling at a moderate pace upon the level, and it may have other ten in reserve for high speeds and for hill climbing. No engineer and no dynamical expert would consider it correct to call the power of the car a force. It is true that the force or pressure of the petrol explosions is a factor in determining the power, but it is by no means the only one. Similarly the force of the muscular contractions of the heart is not the only factor in the determination of its power to do useful work for the circulation. No work is done by a force, however great or however long it may be exerted, unless something be moved by it. The force of gravitation between the sun and the earth, if the relativists will permit us to use the term, does no work so long as it does not increase the earth's mean velocity. A forceful contraction of the heart muscle does no work for the circulation if it drives half the content of the heart into the veins and the other half into the arteries; the blood as a whole is not moved.

The terms "energy," "power," and "force" in their metaphorical senses are much abused by literary men, being, in fact, treated as if they were synonyms.

If Sir James Mackenzie would substitute "power" for "force" in the terms referred to above he would in one respect put himself upon a higher plane than Euclid, being *ab omni naevo vindictatus*.—I am, etc.,

Serowe, Bechuanaaland Protectorate,
South Africa, May 22nd.

P. D. STRACHAN.

THE CASE OF MR. F. W. AXHAM.

We published in the JOURNAL of June 10th a letter from Dr. C. O. Hawthorne suggesting that attention should be directed to the position of Mr. F. W. Axham, whose name was removed some years ago from the *Medical Register* because of his active association with the work of Mr. H. A. Barker, an unregistered practitioner. On June 17th another correspondent, Dr. J. S. Manson, indicated a wish to know the names of the leading members of the medical profession to whom, it was said, the knighthood lately conferred on Mr. Barker owed, in part, its origin. Dr. Hawthorne, however, in his reply printed last week, asked to be excused from entering on controversial issues. We have since received communications upon this subject from several medical men, each of whom includes among other matters an answer to Dr. Manson's inquiry. The most explicit of these correspondents is Dr. L. Edward Williams, who reproduces verbatim a letter in commendation of Mr. Barker's war services, which he states was forwarded to the Prime Minister on November 5th, and was signed by Sir Henry Morris, Sir Alfred Fripp, Sir W. Arbuthnot Lane, Sir Bruce Bruce-Porter, and Sir Joseph Skevington. We take this opportunity of associating ourselves with Dr. Hawthorne in his desire to exclude controversial issues from the discussion to which his letter has given rise.

The Services.

LIEUT.-COL. FREDERICK O'KINEALY, C.I.E., I.M.S., chief medical officer to the Prince of Wales during His Royal Highness's Indian tour, has, on the occasion of the Prince's return, been appointed a Commander of the Order of the British Empire. On the same occasion Subadar Hira Singh, Rai Bahadur, Indian Medical Department, has been made a member of the Order.

DEATHS IN THE SERVICES.

Inspector-General Belgrave Ninnis, C.V.O., R.N. (retired), died at Streatham on June 18th, aged 84. He was the fourth son of the late Paul Ninnis of St. Austell, Cornwall. After taking the M.R.C.S. and graduating M.D. St. Andrews in 1861, he entered the navy as assistant surgeon in the same year, attained the rank of Deputy Inspector-General on May 5th, 1883, and retired, with an honorary step as Inspector-General, on September 1st, 1897. He served as naturalist on the imperial and colonial surveying schooner *Beatrice* on a survey expedition to the northern territory of Australia in 1854-66, receiving the thanks of the Legislative

Assembly of South Australia; as staff-surgeon of H.M.S. *Discovery*, Captain Stephen, in the arctic expedition of 1875-76, under Captain Sir George Nares, receiving the Arctic medal; and was awarded the Sir Gilbert Blane medal in 1880. On June 14th, 1912, he received the C.V.O. He was a Fellow of the Royal Geographical Society and of the Society of Antiquaries. He was the author of *Remarks on the Ethnology, Natural History, Meteorology, and Native Population of North Australia*; of a report on diseases incidental to the Eskimo dogs of Smith's Sound, their diagnosis and treatment; and of a memorandum on the Welsh colony of Chubut, South America. He married Ada Jane, daughter of James Sutton, of Streatham, by whom he had two sons and one daughter.

Surgeon-Major Reginald Croft Lover, R.A.M.C. (retired), died at Denton House, Isfley, Oxford, on June 6th. He was born in London on September 13th, 1837, took the M.R.C.S. in 1859, and the M.B. Lond. in 1860, and entered the army as assistant surgeon in October, 1860. He served for some time in the 7th Hussars. He became surgeon-major in 1875, and retired on half-pay in May, 1877; he was afterwards for many years in charge of army medical work at Oxford.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At the second of the two congregations held on June 29th the following medical degrees were conferred:

M.D.—J. de B. Daly, A. B. Appleton.

M.B., B.Ch.—E. Bryceson.

M.B.—F. B. Smith.

B.Sc.—B. E. Jerwood.

The following candidates have been approved at the examinations indicated:

THIRD M.B., B.Ch.—*Part I. Surgery, Midwifery, and Gynaecology*: W. F. T. Adams, E. B. Brooke, A. E. Clark-Kenedy, B. H. Cole, L. B. Cole, A. L. Crookford, C. B. S. Fuller, H. D. Gardoer, J. H. Gough, C. A. Horder, L. Lawn, J. H. Le Brasseur, G. S. Lund, F. H. Mather, T. D. Morgao, C. P. Oliver, C. V. Patrick, C. J. Penny, H. E. K. Reynolds, A. G. Story, J. A. Struthers, F. B. Sudbury, E. Tagoe, C. G. Taylor, T. M. Thomas, G. D. Thomson, N. G. Thomsoo, R. H. Yolland.

Part II. Medicine, Pathology, and Pharmacology: A. B. Bratton, S. P. Castelli, H. Corsi, F. C. Cozens, J. C. Davies, L. S. Fr. H. D. Gardoer, H. L. Garson, A. A. Gemmell, J. C. N. Harris, H. J. H. Hoodley, R. C. Hawitt, T. L. Hillier, A. G. F. McArthur, T. D. Morgan, B. Mountain, A. D. Porter, A. E. Roche, H. W. Taylor, C. E. Whitting, D. W. Wianicott.

UNIVERSITY OF LONDON.

As briefly announced in our last issue, the Senate of the University has elected Mr. H. J. Waring, M.S., M.B., B.Sc., F.R.C.S., Dean of the Faculty of Medicine, and Vice-President of St. Bartholomew's Hospital Medical College, to be Vice-Chancellor for 1922-23, in succession to Sir Sydney Russell-Wells, M.D. A cordial vote of thanks has been accorded to Sir S. Russell-Wells for the services he had rendered to the University as Vice-Chancellor since December, 1919.

Mr. J. H. Woodger, B.Sc. Lond., has been appointed, as from July 1st next, to the University Readership in Biology, tenable at Middlesex Hospital Medical School.

The Lindley Studentship for 1922, value £120 and tenable in the Physiological Laboratory, has been awarded to Miss M. J. Wilson-Smith, B.Sc.; and the University Studentship in Physiology for 1922-23, value £50 and tenable in the Physiological Laboratory of the University or of one of its schools, to Miss M. M. A. Murray, B.Sc.

UNIVERSITY OF GLASGOW.

COMMEMORATION DAY AND GRADUATION CEREMONY.

COMMEMORATION DAY was observed at Glasgow University on June 22nd, when the customary oration was delivered by Professor Bryce, who chose for his subject "William Hunter and his museum."

Professor Bryce said that the bequest of William Hunter to Glasgow University of his library, coin cabinet, his small collection of pictures, and his zoological, geological, and ethnological specimens and anatomical preparations, which formed his museum, was the most valuable individual bequest which the university had ever received. The last twenty-five years had opened up new vistas; additions had been made to the collections in greater numbers than in any previous period, and a sum of money was now available annually for Treasury grants sufficient to carry out with some degree of adequacy the intentions of its founder for the utilization and extension of the museum, so that this generation was privileged beyond its predecessors. William Hunter was destined by his parents for the ministry, but he devoted himself to science, and left Glasgow University to become apprenticed to Dr. Cullen, afterwards professor of medicine. He turned to Edinburgh for his theoretical medical training, but the lure of London and a greater ambition carried him across the border. He was 21 when he went to London, and within ten years had made himself a leading teacher in the metropolis, and by the time he was 42 he had built up a very large and lucrative practice, was physician extraordinary to the Queen, and a person of weight and influence in the country. A study of the museum in all of its departments indicated that William Hunter in founding it had intended that it should be organized for historical, literary, and scientific research, and that it should be extended with the growth of knowledge. They were forced to admit that his aim in presenting the museum to Glasgow had been but partially realized; but he was convinced that the growth latterly had been in the right direction, and the

Hunterian anatomical preparations now displayed in the anatomical museum were placed and utilized as William Hunter intended they should be. The natural history section, greatly enriched under Professor Graham Kerr, would soon be transferred to a zoological museum, and space would then be available for the valuable geological collections constantly expanding under Professor Gregory.

Following Professor Bryce's oration a graduation ceremony took place, at which a large number of distinguished personages received honorary degrees, including M. Venzelos, M. Raemaekers, and the Bishop of Manchester. It was announced that the fund for promoting the welfare of students by the provision of hostels, the enlargement of the unions, and the equipment of the athletic ground had now reached a sum of £5,000.

At a graduation ceremony held on June 21st the degree of Doctor of Medicine (with high commendation) was conferred *in absentia* on Cecilia Shiskin.

UNIVERSITY OF SHEFFIELD.

The following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B. Margaret I. Cannon,
Dora Cocker, with, Clara D.
Tingle, F. A.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

At a meeting of the Royal College of Physicians of Edinburgh, held on June 20th, with Sir Robert Philip, president, in the chair, the Victoria Jubilee Cullen Prize "for the greatest benefit done to practical medicine" was awarded equally to Dr. John Thomson and Dr. Norman Walker.

Medical News.

THE special post-graduate course on diseases of children arranged by the Fellowship of Medicine and Post-Graduate Medical Association will begin, as already announced, on Monday next, July 3rd, and will continue throughout the week. The following hospitals will take part: East London Hospital for Children, Paddington Green Children's Hospital, Victoria Hospital for Children, Queen's Hospital for Children, and St. Marylebone General Dispensary, and the fee for the course is £4 4s. Those desiring to attend should apply to the Secretary to the Fellowship at No. 1, Wimpole Street, W.1. The next post-graduate lecture will be delivered by Dr. J. Strickland Goodall in the West Lecture Hall of the Royal Society of Medicine at 5 p.m. on Monday, July 3rd, the subject being "So-called functional diseases of the heart."

THE Association of British Chemical Manufacturers arranged an admirable little exhibition last week at Caxton House, Westminster, with a view chiefly to impressing upon members of Parliament the manifold applications of the fine chemical industry to the needs of the State. More than two thousand fine chemicals are now manufactured in Great Britain, and the most important of these were on exhibition, together with some pictorial indication of their various uses. The application to tropical and general medicine and surgery of those drugs of which fine chemicals are the basis was demonstrated with the aid of maps showing the geographical distribution of the diseases in which the drugs in question have been found effective. The many uses of salicylic acid were demonstrated, and another example of the same kind was vanillin, a by-product of the gas industry, obtained from phenol, and used in the preparation of certain kinds of confectionery as a flavouring agent. Many fine chemicals, indeed, are by-products of the gas industry, including benzyl acetate, used in making perfumes. A section of the exhibition was devoted to rare earths, and another to photographic developers, including the metol developer used in x-ray work. A large proportion of the fine chemicals were not manufactured in this country before the war, but the exhibition suggested that the fine chemical industry is now well established.

At the meeting of the Society for the Study of Inebriety to be held at 11, Chandos Street, W.1, on Tuesday, July 11th, at 4 p.m., Mr. C. J. Bond, C.M.G., F.R.C.S., will deliver his presidential address on the influence of hospitals on temperance reform.

As announced in our advertisement columns, the Streatfeild Research Scholarship founded by Mrs. Eliza Streatfeild for the promotion of research in medicine and surgery is about to be awarded. The scholarship, with an emolument of probably £250 per annum, is tenable for three years at the discretion of the committee. Applications, stating nature and place of proposed research, and status of the applicant, should be addressed to the Registrar, Royal College of Physicians of London, Pall Mall East, S.W.1, by Monday, October 2nd, and marked "Streatfeild Scholarship."

MR. N. BISHOP HARMAN, M.B., F.R.C.S., has been elected a corresponding member of the Société Nationale des Sciences Naturelles et Mathématiques de Cherbourg in recognition of his researches into the origin of the facial musculature.

THE annual general meeting of the Professional Classes Aid Council will be held at Aubrey House, Campden Hill, W.8, on Wednesday, July 5th, at 5.30 p.m., under the chairmanship of Lord Phillimore.

A MEETING of the Tuberculous Society will be held on Monday, July 3rd, at 7.30 p.m., at the Margaret Street Hospital, W. 1, when a discussion on "Care work" will be opened by Dr. J. Sorloiy.

ON the occasion of Founders' Day the Lord Mayor, the Lady Mayoress, the sheriffs and their wives visited St. Andrew's Hospital, Dollis Hill. Sir Norman Moore, Bt., thanked, on behalf of the hospital authorities, the City magistrates for their visit. In responding, the Lord Mayor expressed his satisfaction with all he had seen. This hospital for patients chiefly of the professional and middle classes, irrespective of creed or nationality, supplied a great want, and it was a pity it was not better known.

THE twenty-third annual meeting of the Lebanon Hospital for Mental Disease (Syria) took place at the house of the Royal Society of Medicine on June 1st. The director's report showed that the admissions (213) had doubled in number in two years, many soldiers of different nationalities being admitted for short periods of treatment. The chairman (Dr. Fortescue Fox) called attention to the large proportion (66 per cent.) of cases recovered or relieved, due to the early treatment given. All the patients entered voluntarily, without certification and on a paying basis. The duration of treatment for 136 cases out of 172 discharged was less than three months, and the commonest cause of breakdown, "prolonged mental and physical strain." The hospital had become a teaching centre under the American University of Beyrouit, and it was hoped that knowledge and experience of early treatment of mental disorders would be spread into neighbouring countries, where at present only barbarous methods prevailed.

THE latest catalogue the "Solus" Electrical Co. (Judd Street, London) describes a number of pieces of x-ray apparatus of an original character. The illustrations are especially good. A high tension overhead switch for use with the Coolidge tube, and a piece of apparatus for fixing the head for sinus work, seem to be worthy of special mention. This firm supplies tubes and all kinds of x-ray apparatus.

THIS year the Victorian Order of Nurses for Canada celebrates its twenty-fifth anniversary as a voluntary national nursing service. The annual report shows that it is doing most valuable work throughout Canada; but for its services trained nurses would not be available for thousands of needy patients. During the past year a total of over half a million visits were made by its nursing staff, 16,165 maternity cases were attended, and 20,828 visits were paid to expectant mothers, and 52,562 for child welfare.

THE Flemish scientific congresses will be held this year at Bruges, from July 30th to August 7th. More than eighty communications and lectures are announced, on scientific and medical subjects, and many eminent scientists and medical men are to take part in the congresses. At the same time an exhibition will be held of medical and surgical instruments of all kinds, and of scientific books. The general secretary is Dr. G. Joukebeere, O.B.E., 18, Elisabethlaan, Bruges, Belgium.

DR. RAY LYMAN WILBUR has been chosen president-elect of the American Medical Association for the ensuing year. Dr. Wilbur is president of Stanford University, California, and was formerly professor of medicine in the medical school of that university, of which he is a graduate in arts and medicine. He was president of the American Academy of Medicine in 1912 and 1913, and during the war was head of a division of the United States Food Administration.

SINCE 1921 pellagra and cancer have been made notifiable diseases in Venezuela.

ON the occasion of the celebration of the first centenary of Brazilian independence next August the first Brazilian Congress on Infant Welfare will be held at Rio de Janeiro.

A POST-GRADUATE course on oto-rhino-laryngology will be held under the direction of Professor Moure and Dr. Portmann, of Bordeaux, from July 24th to August 5th; the fee is 150 francs, and particulars may be had from the secretary of the Faculty of Medicine, Bordeaux.

THE number of persons suffering from tuberculosis in Switzerland is estimated at 80,000. The annual death-rate from tuberculosis amounts to 20 per 10,000 inhabitants, and the total number of deaths from tuberculosis is about 8,000 among 50,000 to 55,000 deaths from all causes.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL, SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737; Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

TREATMENT OF PSORIASIS.

THE following are among the replies received to the inquiry from "A. B. S." published on June 17th (p. 982):

Dr. J. L. RENTOUL (28, University Square, Belfast), writes: Psoriasis is sometimes benefited by vaccine treatment, and, if all else fails, it should, I think, have a trial. The vaccine I use is one of *Staphylococcus albus* and *aureus*, both of which I have isolated from the skin below a "rippo crust." If "A. B. S." cares to try it, and writes to me, I will send him some.

Dr. J. CARDEW BEDWELL (Assistant School Medical Officer) writes that numerous cases of psoriasis have been very successfully treated at the Chesterfield School Clinic by giving one 1/2-pastillo dose of x-rays to the worst areas. He adds: We formerly gave two or three 1/4-pastillo doses to each case, but find now that one 1/2-pastillo dose seems more efficacious.

Dr. STANLEY E. DENYER, C.M.G. (Hull), reports the case of a man aged 43, who had had psoriasis for eighteen years; the rash was very severe over the back, abdomen, head, nails, left knee, both elbows. "He had to spend one hour every night in a bath getting the scales off. The skin cracked and bled. He had seen many doctors, but had not improved; the case certainly looked hopeless. I suggested that a vaccine might be tried, but would not promise any relief. He agreed, and I made a culture from his skin, and prepared a vaccine of *Staphylococcus albus*, 50 and 500 million per c.c.m. I began with 12½ million, increasing to 18 and 25 million, and so on. He began to improve in many minor ways, such as less pain and irritation, less cracking of the skin. I continued this for four months, and then put him on arsenic and thyroid tablets gr. i. Not much general improvement followed until the March of the next year, when, instead of the rash increasing, it improved rapidly and nearly disappeared. My theory in this case was that the protection set up by the vaccine in the blood was stronger than the yearly incidence of psoriasis. I have lost sight of the patient since, so am unable to say if the protection was permanent."

Dr. STANDISH J. WATSON (Abercraze) writes: I would suggest he tries a course of cyllin ointment combined with cyllin lotion, the lotion being the most important of the two. I have had a very satisfactory result with this treatment in a very similar case to the one he describes.

INCOME TAX.

"A. B. C." states that the inspector of taxes has asked him to supply a "certificated copy of his income for the past year."

*** The inspector has no legal right to require statements supplied for income tax purposes to be certified by an accountant, although the Commissioners might have that authority if the assessment were appealed against by "A. B. C." Unless there are special circumstances, we do not consider that the independent certification of a practitioner's statement is a reasonable requirement, seeing that the matter is comparatively simple as compared with trade or manufacturing accounts. We should advise "A. B. C." to send in a carefully compiled statement and offer to support it by production of his books.

"R. C. P." inquires how the amount allowable for locomotion expenses should be calculated where the car is partly employed on non-professional uses.

*** The only practicable basis seems to be to calculate the total cost of the running, including licences, tyre replacements, etc.,

and to divide it between professional and private use on a mileage basis. This, however, necessitates the keeping of careful records. Another possibility is to calculate the cost of an alternative means of locomotion—for example, hiring or train service; that method is sometimes useful as supporting the reasonableness of a result arrived at on the mileage basis.

"J. B." bought a second-hand 14 h.p. car (original price £360) in 1914 for £149, and sold it in February, 1922, for £10, when buying a new car of 10.5 h.p. for £390.

Assuming the two cars to be of the same or equivalent makes the allowance due would work out as follows:

Original cost of old 14-h.p. car...	£	360
Estimated cost of new car in February, 1922, of similar h.p., £350 × 14/10.5	£	520
Estimated equivalent second-hand cost, £520 × 10.5/14	£	213
Allowance is £213 - £50	£	163

that sum to be regarded as a professional expense of the year in which the expenditure was incurred.

LETTERS, NOTES, ETC.

"THE ETIOLOGY OF CANCER."

Dr. MARTIN J. CHRYVERS (Manchester) writes: The leading article headed as above in the BRITISH MEDICAL JOURNAL of June 17th contains the following sentence: "Above all, closer co-operation between the research officers of the central departments and insurance practitioners holds out the promise of valuable clinico-statistical investigations." This statement has tempted me—though I have never been an insurance practitioner, but have been in general practice for over a quarter of a century—to be bold enough to mention a conclusion I have long since come to with reference to cancer, and it is this—that the chief predisposing cause is rheumatism, whether incipient (as it of course can be) or otherwise. I believe nearly all fibroid growths, including those of the skin and uterus, have a similar origin; whether this conclusion turns out to be right or wrong, I may state that I have not come to it without prolonged clinical observation, and I think the matter is worthy of further investigation.

INSECTS IN AN AUDITORY MEATUS.

Dr. JAMES VAN MILLINGEN writes: Dr. Arthur Sheard's experience of a cockroach in the nasal passages brings to my mind the case of a farmer, aged 75, in the West Highlands of Scotland, who had suffered from deafness in one ear for a period of over 30 years. In syringing out the ear I brought out a full-sized wasp in a perfect state of preservation and completely encased in wax. The man recollected that thirty years previously, whilst working in the hayfields, he experienced a sudden and excruciating pain in the ear, which did not last long enough to prevent him from continuing at his work on that day. The auditory meatus were remarkably large, and the canals were not tortuous.

PROFESSIONAL SECRECY.

WE are indebted to Dr. James Holmes, of Bury, for the following anecdote of an old practitioner who died many years ago, but whom he can just remember. This Dr. C. was a great stickler for what he thought was right, and especially strong on professional secrecy. The tale is as follows: "Dr. C. was attending a Mrs. D., a great friend of his wife. One evening his wife asked him how Mrs. D. was. In place of a direct answer he rang the bell; when the footman appeared he said: 'Give Mrs. C.'s compliments to Mrs. D., and inquire how she is.'"

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 27, 30, 31, 32, and 33 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 28 and 29.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 8.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *posteo restante* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

1. Action of Quinidine Sulphate in Auricular Fibrillation.

R. WYBAUW (*Arch. des mal. du cœur, des vaisseaux et du sang*, April, 1922) refers to his former publication (with DUMONT and JOOS) in *La Polyclinique* (Brussels, March, 1921) of a series of cases of persistent auricular fibrillation. In half the cases the cardiac rhythm was restored, as shown by electrocardiograms, but the restoration of normal rhythm is not a cure, the patient returns to his former condition, and the breakdown of compensation is only delayed. "Since then, the remedy has been used regularly at the Brussels Polyclinic; the positive results and the controls have maintained an analogous ratio, and yet, without the test of experience, we cannot at present differentiate between those cases which react favourably and others." He now continues the administration of quinidine for some weeks after the restoration of normal rhythm, because fibrillation is apt to recur, especially when some slight infection supervenes—for example, coryza or transient enteritis. He commences with a moderately large dose—1.25 to 1.50 grams per dlem for three or four days. If the beat becomes regular 1 gram per dlem is given for one to two weeks. Then digitalis (infusion of 1 gram of powdered leaves) and quinidine are given alternately, each for a period of four or five days. He describes the case of a man who had suffered for seven months from precordial pain, dyspnoea on exertion, and violent palpitation. Blood pressure = 130 to 100 mm. Hg approximately. Both sides of the heart were much hypertrophied; heart sounds were normal, but action very rapid. Digitalis infusion (= 1 gram of powdered leaves in forty-eight hours) was prescribed and continued for seventy-two hours longer. Heart action became slightly slower. Then 1.5 grams quinidine sulphate were given daily for two days. On the third day the pulse was quite regular = 96 per minute. The patient was much easier and free from pain. Quinidine was given regularly for ten days more, when the pulse was regular and had fallen to 76. Four days after, the pulse, still regular, had risen to 156 per minute. The author gives three cardiograms which show remarkable changes in "P" and "R" waves before and after administration of quinidine. Pulsus alternans developed, and further attempts to retard the pulse failed. All treatment was stopped and at the end of three months the pulse again became irregular. Quinidine restored regularity again, but the reaction was rapid and the "P" wave still negative. Six months after admission a third course of quinidine slowed and regulated the pulse, and the "P" wave became positive. Treatment was continued, when tonsillitis supervened and caused a relapse, although the patient felt well. A fourth course of quinidine in the following month resulted in permanent improvement. Wybauw shows that his results confirm clinically the latest views of Lewis (*Heart*, 1921) and of De Boer on the mechanism of auricular fibrillation, and compares the action of digitalis, which diminishes the conductivity of the auriculo-ventricular bundle, with that of quinidine, which prolongs the "refractory period." A clear analysis of the clinical symptoms and interpretation of the cardiograms follow, and he comments on the importance of the study of the therapeutic action of quinidine, the discovery of which coincided with the recent advances in cardiology.

2. Dermatitis from Dyed Furs.

RASCH (*Ugeskrift for Læger*, April 13th, 1922) has observed within two months nine cases of dermatitis of the face and neck which he traced to the wearing of dyed furs. All the patients were women between the ages of 24 and 47, and in two cases the disease was simply a recurrent itching erythema of the chin. In other cases it was eczematous or lichenoid, but common to all the different types of rash was the distribution, and the longest diameter of each patch was parallel with the line of the jaw or across the neck. In one case the erythema was vesicular, and the lips were swollen. In another case itching and swelling of the eyelids occurred. Some of the patients stated that the rash was worst after they had been out of doors for some time. All the patients had worn for some weeks or months new coats trimmed with a brown fur known to the trade as "biberette." In one case the peccant fur was sold under the name of "sliade." These furs were probably rabbit skins treated so as to resemble beaver. The author refers to a publication by Blaschko (*Deut. med. Woch.*, 1913, No. 49) in which he dis-

cussed the use in the German fur industry of the drug para phenylenediamin, which turns fur brown, and the author suggests that this highly irritating substance is responsible for his cases. The rash in every case cleared up within five to fourteen days of discarding the furs, and in the meantime he treated them with powders, compresses, zinc lotions, and zinc pastes. Many of the author's colleagues have seen similar cases, and the condition is evidently not rare.

3. Infantile Splenic Anaemia.

DE STEFANO (*La Pediatria*, May 1st, 1922) publishes 23 cases of infantile splenic anaemia, and attempts to give the cause of the disease. In 13 syphilis alone appeared sufficient to account for the condition, in 6 the syphilis was associated with tuberculosis, in 2 tuberculosis alone, and in 2 the cause was unknown. These findings correspond with the reports of other observers. Malaria or leishmaniasis accounts for some cases. Most of the cases show a certain amount of pyrexia, but variable in type and often due to intercurrent disease, and never as typical as that seen in leishmaniasis. As regards the blood, leucopenia was noted in 10 out of 19 cases. In the tuberculous cases more or less marked lymphocytosis was present. The exact mechanism of the production of the anaemia is not easy to determine. It may be due to congenital inheritance, to congenital dystrophy of the haemopoietic organs, or the toxins transmitted through the mother's milk. Excluding the cases of direct transmission of syphilis or tubercle with localization in the haemopoietic organs the author believes most cases can best be understood by assuming an hereditary dystrophy of the blood-making system.

4. Flavine in Treatment of Eczema.

FERGUSON SMITH (*Brit. Journ. of Derm. and Syph.*, May, 1922) has tried the effect of substituting flavine for boric acid in the starch poultice treatment of eczema, so commonly practised in Scotland. Boric acid has been used hitherto because other antiseptics to be efficient have to be present in strengths which the inflamed skin will not tolerate, but amongst the flavines are found chemical substances which are comparatively non-irritating in efficient concentration, and whose activity is enhanced rather than diminished in the presence of serous discharge. The flavine starch poultice is made in the following way: Four table-spoonfuls of rice starch and 0.6 gram of acriflavine are mixed with a little cold water, one pint of boiling water is added, and the mixture is boiled with constant stirring until it thickens, and when nearly cold it is poured on to the dressing cloth so as to form a layer half an inch thick. When quite cold and set it is covered with a single layer of gauze or butter muslin and applied to the part. It is changed three or four times a day, and at each change the part is bathed with acriflavine 1 in 1,000 in 0.85 per cent. NaCl, and the treatment should be continued until more stimulating remedies may safely be applied. Flavine starch poultices have proved very useful in treating obstinate cases of "seborrhoeic" eczema of the head and groin.

5. Chronic Dysentery and Severe Colitis.

KLING (*Wien. klin. Woch.*, March 16th and 23rd, 1922) states that hitherto no cases have been recorded in which the transformation of acute dysentery into severe colitis has been observed. He therefore reports 11 cases in which a direct transformation of the lesions of the acute stage of typical bacillary dysentery into those of severe colitis could be followed by means of a series of rectoscopic examinations. All the cases occurred during an epidemic of bacillary dysentery at Vienna in the summer of 1920 and the following months. During this time 1,439 cases were admitted to Kling's hospital. In 102 cases, or 7.5 per cent., the course of the dysenteric attack was prolonged in consequence of a sequel such as mild colitis, dyspepsia, articular rheumatism, etc. Only 0.4 per cent. of all the cases of acute dysentery and 9 per cent. of the cases of chronic dysentery developed severe colitis; 9 occurred in women and only 2 in men, suggesting that the female sex is much more prone to the transformation of dysentery into severe colitis. The ages of the patients ranged from 18 to 60. The following causes for the transformation could be incriminated: (1) lack of treatment and nursing during the acute stage; (2) an inferior constitution, shown by an asthenic disposition, chlorosis, and congenital malformation; (3) concurrent diseases.

6. The Mode of Infection by Ascaris.

F. FÜLLEBORN (*Klinische Wochenschrift*, May 13th, 1922) has collated the observations of many parasitologists and has summarized his own work on this subject since 1911. He states that ascarides infesting mankind and pigs are identical, but that belascaris, found in dogs, is of a different species. The author found that ascaris ova in human or pigs' faeces, deposited in moist garden soil and swallowed by another animal, quickly discharged their freely motile larvae, which, in a few hours, penetrate the wall of the alimentary canal, reach a branch of the portal vein, and travel thence to the lungs. One plate shows massive infection with numerous haemorrhages on the surface of the lungs of a young guinea-pig, nineteen hours after infection with pig's ascaris ova; another shows a collection of young ascarides coiled up in the bronchus of a rabbit, fifteen days after ingestion of eggs. An ascaris larva was found in a cerebral capillary of a guinea-pig twenty-five hours after infection. Fülleborn insists that ascaris infection must be regarded as a general systemic condition, as, in addition to these plates, others show a young ascaris larva in a rat's liver, a belascaris cyst in a dog's cardiac muscle, and blood-clot in a convoluted tubule of a guinea-pig's kidney nineteen hours after infection with the eggs; he has observed haematuria in several of his experimental animals, and has also found free ascaris larvae ("resembling strongyloides-*Illaria* forms") in the peritoneal and pleural cavities. The larvae appear to take one of two courses: (1) those which pierce the pulmonary alveolar epithelium, travel up the air passages, often setting up bronchitis, and are eventually swallowed with the saliva and so return to the intestine, where they become mature; or (2) those which are carried in the pulmonary circulation to the left ventricle, reach the systemic circulation, and their subsequent behaviour resembles that of *Trichinella spiralis*. Fülleborn confirms the observations of Stewart and Ramsom, and alludes to cases of bronchitis and bronchopneumonia, and to the effects of toxins liberated in the course of pulmonary or cerebral infections by *Ascaris lumbricoides*.

SURGERY.

7. Pneumococcal Peritonitis.

MCCARTNEY and FRASER (*British Journal of Surgery*, April, 1922) point out that about 2 per cent. of the abdominal emergencies of childhood are due to pneumococcal infection, and this ranks as one of the most serious abdominal emergencies in children. The mortality is high, being 65 per cent. for the past twenty years. There is an essential division of pneumococcal peritonitis into two classes—primary and secondary. The secondary form follows previous infection elsewhere, such as lungs and pleurae; the primary type is peculiar to the female sex. The peritoneal cavity of the female possesses one characteristic which distinguishes it from that of the male—it communicates with the exterior through the medium of the genital tract. It is suggested that this channel may be the medium through which the infection enters the peritoneal cavity. The age of incidence is most frequently the fifth and sixth years; perhaps this is related to the alkaline reaction of the vaginal secretion, as after that period it becomes acid. The condition begins as a pelvic peritonitis with pain and frequency of micturition, and pain referred to the suprapubic region. This is further shown in early cases, where the condition is found localized around the Fallopian orifices. Three varieties of the primary disease are recognized—fulminating, acute, and chronic. The striking manifestations of the condition are excessive vomiting in the early stage, diarrhoea, and bladder symptoms. With regard to treatment, early operation affords the best prospects of recovery: drainage of the peritoneal cavity under gas and oxygen anaesthesia, with the addition of blood transfusion. Transfusion is best done when the signs of septicaemia are beginning to appear. The adoption of this method has greatly diminished the mortality figures.

8. Shadowless Renal Calculi.

GRAVES (*Annals of Surgery*, April, 1922) states that it is common knowledge that a small percentage of renal calculi fail to cast shadows in an x-ray plate; probably 80 to 90 per cent. of stones will show. These calculi, which present no greater density than the body soft parts, are chiefly of uric acid or urate composition. Concerning the visibility of cystin calculi, there seems to be little accurate information; general opinion classifies them as shadow-casting stones. He reports a case of a pure cystin calculus which failed to reveal itself in two x-ray examinations. Experimental capsules containing cystin and swallowed failed to show on x-ray examination. The opacity of a calculus is determined not alone by its composition but by its thickness and structure as well. It is

possible for two stones of the same composition to present different degrees of permeability to the x rays, one being of loose texture, the other perhaps harder and more compact. Pure cystin calculi, with their characteristic loosely knit structure, should be classified among the relatively invisible stones. Admixture with inorganic substances may account for exceptions to this rule, and may explain the results of other observers. In cases of doubt, by the injection of an opaque solution into the ureter and renal pelvis, invisible stones may sometimes be shown by negativity.

9. Retrograde Intussusception of the Small Intestine after Gastro-enterostomy.

LUNNBERG (*Acta Chirurgica Scandinavica*, April 29th, 1922) has observed one case, and collected the records of eight other cases, in which gastro-enterostomy was followed by retrograde invagination of the small intestine into, or towards, the artificial opening in the stomach. In his own case this accident happened nearly ten years after anterior gastro-enterostomy had been performed, and the patient was too debilitated to be operated on, dying soon after admission to hospital. The only case in which this condition was diagnosed before operation or death was Baumann's, in which a history of a similar accident to the patient eight weeks earlier greatly facilitated the diagnosis. The prognosis depends entirely on the treatment; the cases operated on recovered, those not operated on died within a few days. The mechanism of this condition is practically the same as for other forms of intussusception, and an additional factor may possibly be found in the comparative speed with which food in the stomach is emptied into the small intestine which may be unnaturally stimulated by this partially digested food. As Baumann has shown, ascending intussusception of the gut is very rare, descending intussusception being approximately 200 times more common.

10. Complications following Removal of Tonsils.

MARTIN (*Journ. Laryngol. and Otol.*, February, 1922) summarizes the immediate results of operations for the removal of the tonsils in 14,960 cases operated upon in the ear and throat department of the Royal Infirmary, Edinburgh (1907-20), chiefly from the point of view of estimating the relative risk attending in- or out-patient treatment. In the first 7,133 tonsillectomy was performed in the majority of instances, but from 1914 to 1920 7,575 cases were treated with the guillotine by the Sluder-Whillis-Pybus method, and in the remaining 252 cases the tonsils were dissected out. Of the 7,575 cases 2,524 were treated as in-patients and 5,051 as out-patients. The mortality of the whole series of 14,960 cases was six, one being due to delayed anaesthetic poisoning, one attributed to status lymphaticus, one to septic absorption, and three to bronchopneumonia, associated in one with hyperplasia of the lymphatic tissue. In no case was death due to haemorrhage, and that following the guillotine operation is almost negligible provided no tags of tonsillar tissue are left. During the last ten years (the period of enucleation by guillotine) there was no occurrence of haemorrhage requiring forceps or clamps for its control, while of the 252 operations with scissors and snares five cases of primary haemorrhage occurred, four being slight and controlled by sponges, and the fifth requiring a clamp. Complications occurred so much more frequently in those treated as out-patients, owing to the exposure on the journey home and unsuitable atmospheric conditions (6 arising when the operation was in the summer and 16 when in the winter months), as to justify the discouraging of out-patient treatment, at least in the winter.

11. Scaphoid Scapula.

REIJS (*Nederl. Tijdschr. v. Geneesk.*, February 18th, 1922), who reports an illustrative case, states that the condition of scaphoid scapula—that is, a scapula with a concave vertebral border—was first described in 1910 by Graves, who attributed it to inherited syphilis. This, however, is not the only cause, as Kellner among 50 idiots found scaphoid scapula in 40, only 15 of whom had inherited syphilis. The degenerative character of the deformity is also shown by Drasche, who in the examination of 5,000 school children found 10 to 20 per cent. with this deformity, which was present in 30 per cent. of the mentally deficient. Other causes incriminated are alcohol, tuberculosis, and rickets. Reijs himself found scaphoid scapula in 22 out of 119 school children and in 58 out of 114 mentally defective children. Examination at the Groningen Museum of 32 complete skeletons and 53 loose scapulae showed only three examples among the former and two among the latter—in other words, a much lower frequency than in living subjects. Reijs regards the scaphoid scapula as a sign of degeneration indicating a throwback to lower forms, because a scapula with a convex border is found only in certain primates and in man.

12. Diagnostic Value of Abdominal Pain.

MAX (Canadian Practitioner, April 1st, 1922), believing that every internal condition has an external expression, points out the value of pain, tenderness, and rigidity in the diagnosis of abdominal and pelvic diseases. Intermittent pain is indicative of either neuralgia or obstruction, the former being referred to the surface, relieved by pressure, present along the course of nerves, sharp and darting in character, and increased by cold or lowered vitality; while the latter is intensified by pressure, mainly felt in front, not related to the course of nerves, paroxysmal and wave-like, gradually reaching intensity and then subsiding, and increased by stimulation of peristalsis. An intense, sudden, tearing pain producing collapse with vomiting is common in the rupture of organs permitting the escape of irritating fluid into a healthy peritoneal cavity, as occurs in rupture of ectopic gestation, pyosalpinx, appendix abscess, gall bladder, gastric and duodenal ulcer. In colic the pain is intermittent, and the abdomen is not rigid between the attacks, while in acute abdominal conditions the pain is continuous, and accompanied by tenderness and rigidity. Rigidity over an inflamed viscus does not occur until its peritoneal surface becomes inflamed. In intussusception the pain is intermittent, and it is at the height of the paroxysm that the intussusception is most palpable, because both the pain and the mass are caused by the increased peristalsis. In palpation the hand should be warm, gently applied, and never raised from the abdominal wall, but gradually allowed to creep over the surface while the patient's attention is distracted by questions which require some thought to answer. The combination of pain and tenderness is of value in diagnosis, since in ordinary colic, lead colic, gall stone, renal and ureteral colic there is pain, but no tenderness; while both are present in appendicitis, peritonitis, gall-bladder empyema, or perinephritic abscess.

13. Oral Sepsis in Cancer of the Throat.

MCKENZIE (Journ. Laryngol. and Otol., May, 1922), observing that all the cases coming under his care of cancerous ulcers of the pharynx and oesophagus in which progress was slow were edentulous, and had been so before any symptoms of cancer arose, considers that the slow progress of the growth is due to the fact that the mouth secretions are much less virulently infective when all the teeth have been removed. That treatment by diathermy temporarily improves both the appearance of the ulcer and the resulting symptoms of pain and difficulty in swallowing is explained by its sterilizing action rendering the growth area for a time aseptic. He contends that the progress of the cancerous growth is rendered slow or rapid according to whether the teeth are absent or present, since septic infection exerts a powerfully stimulating influence; and the contention is supported by the fact that most cases of throat cancer die from septicaemia rather than from haemorrhage, asphyxia, or starvation. The extraction, therefore, of all the teeth is advised as a preliminary to all grave surgical operations on the pharynx or oesophagus, and in the palliative treatment of inoperable throat cancer by diathermy.

14. Lesions of the Maxillary Sinus in Neolithic Man.

SIFFRE (Rev. de Laryngol., February 28th, 1922) describes seven cases of maxillary sinus infection found by him in forty-nine specimens of neolithic man found at Guiry. There was no true caries such as is seen to-day. Infection probably started after traumatic injury of the tooth, or in some cases excessive wear, the crown being quite worn down. The maxillary sinuses were perforated in seven cases, and communicated with the dental alveolus or the buccal cavity. Each specimen is described and drawings given of the condition found.

15. Radium Treatment of Tumours of the Bladder and Urethra.

MARION (Journ. d'urolog., March, 1922), who during the last three years has made frequent use of radium in various affections of the urinary tract, draws attention to its haemostatic action in tumours of the bladder and urethra. He records seven cases—six of vesical and one of urethral growth—in which profuse haemorrhage was checked by this means. In addition to its haemostatic action radium caused a distinct atrophy, and in one instance a destruction of the growth. Apart, however, from any curative action, radium is of great value in inoperable tumours, which may give rise to profuse haemorrhage. The technique of its application is very simple. In each case a dose of 10 cg. was introduced by a rubber catheter into the bladder and left for twelve hours. After the application the patients sometimes showed a slight reaction, consisting in a frequent and painful desire to micturate, but never had any severe pain, and the bladder was never injured by the application.

OBSTETRICS AND GYNAECOLOGY.

16. Indications for Caesarean Section.

POLAK and BECK (Surg., Gynecol., and Obstet., May, 1922) speak of a too ready tendency shown at the present day to perform Caesarean section. The operation is attended by a greater mortality and morbidity than other abdominal operations for intrapelvic abnormalities such as myoma and ovarian cyst. From an analysis of 2,000 Caesarean sections performed in American clinics it is reported that in 210 clean cases in which the operation was done before or early in labour and no vaginal examination had been made the mortality was 2.9 per cent.; potentially infected cases (1,260 in number) and frankly infected cases (530) showed percentage mortalities of 6.2 and 11.5 respectively. Caesarean section may be made an operation of election when it is clear that the child's life will be seriously endangered, or the mother's health probably affected seriously, by delivery *per vias naturales*. More general and careful prenatal study will permit of Caesarean section being made with comparative safety in a larger number of cases at an early stage uncomplicated by infection. Apart from pelvic tumours likely to cause insuperable dystocia, absolute indication for abdominal hysterotomy is found only in contracted pelves with a true conjugate of 6 or 6.5 cm. Relative indication may be found in placenta praevia when the foetus is alive, the mother at or near term, the placenta implanted centrally or nearly so, and infection probably absent; occasionally in pre-eclamptic conditions which have resisted medical treatment, provided that pelvic contraction or abnormalities of the soft parts are also present and likely to render vaginal delivery difficult; and in placental abruption (accidental haemorrhage) if the birth passages are totally unprepared.

17. MAGALHAES (Gynecol. et Obstet., 1922, v, 5) finds no contraindication to Caesarean section in cases in which the foetus is living and in which either spontaneous vaginal delivery is impossible or operative vaginal delivery presents real difficulty; he supports his arguments by quotations from the records of the maternity clinic at Rio de Janeiro. For disproportion between foetus and pelvis Caesarean section offers prospects which for the mother are equal, if not superior, to those of forceps delivery or version, and better than those of symphysiotomy, pubiotomy, or embryotomy; the outlook for the foetus is immeasurably superior after abdominal hysterotomy. According to the writer the high forceps operation and pubiotomy are both procedures to be condemned. For cervical rigidity Caesarean section has a better prognosis than metallic dilatation, incisions with the bistoury, or vaginal hysterotomy. For dystocia due to contraction of Bandl's ring, Caesarean section removes the risk of rupture of the uterus, and in the writer's thirteen cases led to one maternal and no foetal deaths. The one death, like many others occurring in dystocia, was attributable to employment of vain tentatives to deliver by forceps or embryotomy. For the writer, Caesarean section is the operation of election in cases of prolapse of the cord, prolapse of a limb in cephalic presentations, and central placenta praevia; and late Caesarean section, even in cases in which, as a result of repeated examination and attempts to deliver, infection is probable if not indeed demonstrable, appears to him to offer less risk to the mother than is the case with other methods of delivery.

18. Tuberculosis of the Reproductive System.

ACCORDING to PESTALOZZA (La Gynecologia Pratica, March, 1922), tuberculosis of the female reproductive organs appears to be especially frequent in Italy, where about 10 per cent. of female subjects of tuberculosis exhibit tuberculous disease in the reproductive organs, and where young women are most commonly and children not rarely affected. The Fallopian tube is the organ most commonly diseased; ovarian tuberculosis is rare, but tuberculous disease of the vaginal portion of the cervix has been observed with increasing frequency of late years. Primary tuberculous affection of the genital organs is extremely rare; in one-third of cases peritoneal and genital tuberculosis coexist, the former being primary and leading to involvement of the reproductive organs either by direct extension or propagation along the lymphatic vessels. In the other cases the genital organs are infected through the blood stream or by extension from neighbouring organs apart from peritoneal involvement. In childhood tuberculous disease of the uterus or adnexa is much more common than is generally supposed; it may prove fatal by giving rise to generalized tuberculosis, or in the process of cure gonital hypoplasia may occur, of which the most frequent sign is uterine atresia. In this way many cases of amenorrhoea and dysmenorrhoea in the adult find their origin. Anatomically, tubal tuberculosis is characterized

by sacculi formation, by cold abscess, or by vegetating or papillary lesions which may or may not be accompanied by ascites; tuberculous endometritis almost invariably fails to pass beyond the internal os, and tuberculosis of the cervix is manifested in papillary excrescences. Clinically the most characteristic symptoms are amenorrhoea (primary or secondary), retarded puberty, with signs of partial or complete uterine atresia, of papillary affection of the cervix, or of chronic adnexal inflammation. Therapeutically, in addition to fresh-air treatment and administration of iodides, amputation of the cervix or enucleation is indicated for tuberculous disease confined to the portio vaginalis or the corporeal endometrium respectively; more radical operation is indicated in the presence of severe pain or prolonged incapacity. Since removal of the adnexa is associated with a mortality of 2 per cent., and of the uterus and adnexa with one of 10 per cent., prolonged preliminary trial of heliotherapy and of radiotherapy—of which latter good reports have been given of late—is recommended.

19. Ascites Complicating Myoma Uteri.

ACCORDING to DUNKHASE (*Zentralbl. f. Gynäk.*, May 6th, 1922), ascites is a more common complication of uterine myoma than is usually recognized: Casanouvo has described it as occurring in 10 per cent. of cases. The writer describes the case of a patient aged 51 who complained of sudden wasting and rapid swelling of the abdomen; 20 litres of ascitic fluid were removed and hysterectomy was performed, the uterus being the site of a large subserous pedunculated myoma. Cure ensued rapidly. The occurrence of ascites in connexion with myoma is to be ascribed to irritation of the omentum, and it is noteworthy that in the case recorded this organ was connected with the myoma by strands of tissue which included several thick and twisted venous stems. The presence of small degrees of ascites does not affect the prognosis in cases of myoma, but considerable accumulations of fluid afford strong indication for speedy operation.

20. Prolapse of the Umbilical Cord.

ACCORDING to SCHWEIZER (*Munch. med. Woch.*, 1922, 3), prolapse of the cord occurred in 1.13 per cent. of 19,000 births at the Leipzig Frauenklinik; foetal mortality was 56 per cent., or 38 per cent. among foetuses which were still living at the time of admission of the mother. Early diagnosis of the condition is all-important. When the cord presents, but has not prolapsed, it is essential to preserve the integrity of the bag of waters as long as possible; rupture of the membranes should be followed at once by vaginal examination and by careful observation of the foetal heart. For prolapse of the cord manual reposition followed by introduction of a dilating bag is a procedure which warrants more frequent trial; the same is true of vaginal hysterotomy. Caesarean section is indicated in cases of pelvic contraction, especially in the early stages of labour in primiparae. The quality of the foetal heart sounds is of greater significance as regards prognosis for the child than is the presence or absence of pulsation in the cord. The foetal mortality varies inversely with the extent of cervical dilatation.

PATHOLOGY.

21. Significance of Influenza Bacilli.

BLOOMFIELD (*Johns Hopkins Hosp. Bull.*, May, 1922) is definitely of the opinion that Pfeiffer's bacillus is not the cause of influenza, because, although this organism is commonly recovered from the throats of patients with influenza during an epidemic, there is always an equally high incidence of this organism in other diseases, such as measles, at the same time. The lesions produced by experimental infections with influenza bacillus cultures resemble more closely the post-influenza pneumonias than uncomplicated influenza lesions. Moreover, there is evidence that the bacteria classified as influenza bacilli belong to a heterogeneous group differing widely in their biological characters, whereas it would have been expected that a pandemic would have been caused by a highly virulent strain. What, then, is the significance of *B. influenzae*? A study of the comparative incidence of influenza bacilli at various times has shown that the high incidence of Pfeiffer's bacillus in the throats of healthy people which was present during and after the pandemic has declined to the normal or pre-epidemic figure. A study of the seasonal variance shows that there is no evidence that the incidence of *B. influenzae* in healthy people varies with the incidence of mild respiratory infections. A study of the conditions necessary for the production of the carrier state has shown that the organisms may continue to live and multiply in a focus of infection, such as chronic bronchitis or bronchiectasis; that normal people without any recent history of respiratory disease may harbour *B. influenzae* for

brief or prolonged periods; that great variations have followed the introduction of influenza bacilli experimentally in man, in some cases the bacteria being promptly eliminated and in other cases inducing a carrier state. The author concludes that Pfeiffer's bacilli only possess a partial degree of adaptation to free growth on normal mucous membrane. A variety of acute infections, notably that known as influenza, alter the soil in such a way that Pfeiffer's bacilli are able to become temporarily adapted to widespread growth in affected individuals.

22. The Rapid Diagnosis of Urinary Tuberculosis.

DIRECT examination for the presence of tubercle bacilli in the urine is frequently negative, while injection into a guinea-pig necessitates a delay of four to six weeks before a definite answer can be obtained. In order to obviate these two difficulties, ROCHAIX and BANSSILLON (*C. R. Soc. Biologie*, May 6th, 1922) have resorted to the use of cultural methods, by which they are able to record a high percentage of positive results and a saving of two to three weeks. The medium they employ is Petrof's real-peptone-egg mixture containing 1 in 10,000 gentian violet. The deposit from the centrifuged urine is seeded directly on to several tubes of the medium, and a growth is obtained—if positive—within a fortnight. Although in the great majority of cases the findings have been closely correlated with those obtained by the injection of a guinea-pig, they quote two instances in which the cultures were negative even in the presence of advanced urinary tuberculosis. For this reason they conclude that reliance is only to be placed on positive results, negative ones being of little value—a conclusion, it may be stated, which holds good for a very large number of laboratory tests for the presence of infective disease. In the same number DESPEIGNES records his experiences on the use of Petrof's medium for the rapid diagnosis of genito-urinary tuberculosis. Much the same technique is employed, but instead of seeding the deposit direct on to the medium he subjects it to a preliminary digestion for one hour with 4 per cent. sodium hydrate solution. His results appear to be wholly satisfactory.

23. A New Reaction for Urea and its Clinical Value.

WELTMANN and BARRENSCHEN (*Klinische Wochenschrift*, May 27th, 1922) describe a new reaction for urea. The addition of Ehrlich's aldehyde to the urine produces a greenish-yellow coloration. A marked greenish-yellow coloration is also produced when Ehrlich's aldehyde is added to a watery solution of urea. No other substance occurring in normal urine, except urea, produces this reaction. The authors think the reaction will be of great practical value in estimating the residual nitrogen in blood serum, which has hitherto been a complicated procedure. In carrying out the test, the albumin of the serum is removed by means of 20 per cent. trichloroacetic acid; to 1 c.cm. of the filtrate two drops of Ehrlich's aldehyde are added. A yellowish-green colour is only produced when the residual nitrogen is pathological in amount. A positive reaction indicates an increase of the residual nitrogen. The authors think this reaction will be of value in clinical work, as a rough means of deciding if the residual nitrogen is normal or pathological in amount. Only a small quantity of blood serum is required for the test.

24. Influence of Glycogen on Tumour Grafts of the Mouse.

It is known that glycogen tends to be distributed particularly in cells which are undergoing rapid reproduction, such as those of embryonic tissues and of new growths, and there is some evidence in the case of the latter to suggest that the more malignant the tumour the higher the glycogen content of its cells. Working on the basis of this affinity of the neoplastic cell for glycogen, BORREL and COULON (*C. R. Soc. Biologie*, May 20th, 1922) endeavoured to ascertain whether it would be possible to introduce some protoplasmic poison into the substance of the tumour by combining it with this body. The antiseptic they chose was iodine. A compound of glycogen, extracted from a horse's liver, with Lugol's solution of iodine was prepared and injected into a series of mice which had been inoculated ten days beforehand either with a sarcomatous or with an epithelial graft. The result was that in 50 per cent. of cases the tumour underwent retrogression, following on a course of five or six injections. Control animals which received no injection, and controls which were inoculated with glycogen alone, were studied at the same time. The latter were found to die before the former, presenting larger-sized tumours. Glycogen therefore appears to act as a food substance for the cancerous cells. Mice in which retrogression of the growth had occurred subsequent to the introduction of the glycogen-iodine compound were found to be refractory to subsequent grafts. However successful this method may be with inoculated tumours, the authors admit that it has never yet been able to cause retrogression of spontaneously occurring tumours.

A British Medical Association Lecture ON THE PROBLEM OF THE RADIUM THERAPY OF CANCER.*

BY

ARTHUR BURROWS, M.D. LOND.,

RADIOLOGIST, MANCHESTER AND DISTRICT RADIUM INSTITUTE.

[In the earlier portion of the lecture Dr. Burrows dealt with the physical properties of radium; he then went on as follows:—]

A few facts have been established in respect to the action of radium on cancer cells during the last twenty years. The first is that cancer cells can be destroyed by rays, but this statement is modified by the knowledge that, given a sufficient dose, practically all tissue cells can be killed by radiation, and so arises the second point—namely, that there is a minimum dose which will just kill a cancer cell and will not, as a rule, kill an ordinary tissue cell. This is called the "minimum lethal dose," the "lethal dose," or the "cancer dose." This lethal dose varies with different tumours and different conditions.

Theoretically, given a known quantity of rays, the lethal dose of the cells of a certain cancer, and the size and situation of the tumour to be treated, it is possible to destroy almost any cancer, but unfortunately all these three conditions are variable and are made up of variables. Thus, with regard to rays, the beta rays from radium are not uniform, but are made up of groups of rays which are of different penetrability. Similarly the gamma rays are mixed, as also are α rays. Beta rays can be screened off entirely by using metal plates of a definite thickness, or they may be partially cut off by using thinner or less dense material. It is very difficult to cut off all gamma rays, but certain of them can be eliminated by a process of screening and an attempt made to obtain rays of a certain minimum penetrating power. In the same way by screening and by improving and standardizing apparatus an attempt is made to keep α rays as constant as possible, but unfortunately it is not known exactly what is the right type of ray for each tumour. A few facts are known—for example, that a rodent ulcer will do well with unscreened radium (that is, mostly beta-ray treatment), but gamma-ray treatment is also effective. I think, however, that if beta rays fail in the treatment of a rodent ulcer gamma rays will rarely be successful. Skin diseases are obviously most suited for rays of a longer wave-length. Most rays seem to affect lymphosarcomata, while carcinoma of the tongue as a rule yields best locally to beta rays, but of course with beta rays there is a strong caustic or destructive action. One of the claims of the Erlangen α ray treatment is that a correct ray for the destruction of carcinoma of the cervix of the uterus has been established. But the size, density, and depth of a tumour obviously affect not only the quantity of rays penetrating the whole of a growth—for that can be rectified—but also the quality, which cannot be thus adjusted when radiation is being applied from a distance. The actual insertion of a varying number of suitably screened radium tubes into a tumour is the only method of ensuring uniformity in the quality of the radiation applied. Some tumours are not suitable for the burying of tubes in their substance, and it is then seen how complicated the whole subject is, and how the question of the quality of the rays used, and the dosage, merge into a consideration of the size, density, nature, and position of a tumour.

Lethal Dose.

Assuming that beta rays are used to kill a cancer cell, it is probable that the lethal dose for these would be different from the lethal dose for gamma rays; or, pushing the matter farther, the lethal dose of soft α rays would be different from the lethal dose of hard α rays, as the destructive action of radiations must depend on the quantities of them which are actually stopped in the cells of a growth. Therefore, in fixing a lethal dose for a certain tumour, it must be established for a definite type of ray, and this does not in practical therapy depend altogether upon the operator, but upon the size, nature, and position of the growth he has to radiate. Thus, change the position of the growth by one centimetre and it may be necessary to alter the type of ray used, and

with that the dosage if raying is being carried on from a distance. Then, again, the lethal dose for a tumour may be very near that of the ordinary tissues, and a very fine or no margin left between the quantity and type of rays destroying the normal tissue and the cells of the tumour.

As an example of this last possibility the secondary nodule which may be present on the chest wall following an amputation of the breast may be given. Over this may be stretched a thin and delicate covering of epithelium, and any application of rays given to the nodule may destroy the skin beyond repair long before the tumour cells in the nodule itself are killed.

Nature of the Tumour.

It is an established fact that some tumours are destroyed by rays more easily than others—for example, a small round-celled sarcoma is more easily caused to disappear by irradiation than a squamous-celled carcinoma; but absolute uniformity in respect to the behaviour of groups of growths under radiation does not exist, as other factors, such as the patient's general resistance to tumour growth, or the situation of the tumour, alter its susceptibility to rays and possibly also the stage of development and age of the tumour itself. Is, for instance, a rodent ulcer growing in the skin a different growth from one growing in bone? The same treatment will not cure them both. In fact rodent ulcers of the skin are easily cured by radium; rodent ulcers invading bone are only exceptionally cured.

Nor must the fact be forgotten that rays seem most markedly to affect the reproductive functions of cells. Therefore let the tumour grow quickly, and most often the local growth will rapidly diminish, and vice versa; but unfortunately the local tumour is not the only consideration, for growths such as encephaloid carcinoma of the breast, which grow very rapidly and respond well to radium, soon form secondary deposits, so that the ultimate result is not so good. Or again round-celled sarcomata are usually quoted as types of tumours which respond well to radium treatment, but the more slowly growing and difficult to treat spindle-celled sarcomata with perseverance give the best results in the end.

Size and Density of Tumours.

The size of a tumour is important from several points of view. If a tumour is exceedingly large commonly there is a poor blood supply at the centre (if it is a carcinoma), and there is a great tendency for the tumour to break down and slough under treatment, while at the same time a poor blood supply does not give adequate chance of repair following the treatment. Again, the size of the tumour has a marked effect upon the size of the dose of radiation which is given if an attempt is to be made to destroy all the cells it contains. A small tumour can fairly easily have an even radiation applied throughout its substance, but if it is very large, provided the rays are applied from one direction, the quantity falling on the near side of the tumour will be very much greater than that emerging from the far side. It is also apparent that the density of the growth will have a similar effect, for the denser the tumour the greater will be the difference between the entering and emerging rays.

In the early days of radium treatment Wickham and Degrais suggested the method of cross-fire as one of the means of getting over this difficulty—for instance, if a tumour can be treated from two sides, all other factors being equal, double the dose can be given to the tumour by applying radium to it on those two sides. If the tumour is accessible it may be radiated from more than two sides. What is done by the Erlangen method of α -ray treatment is very much the same thing. In order to get a sufficient quantity of α rays to the tumour, rays are directed through several different areas of skin towards the tumour, which areas are called "ports of entry." It is thus seen that the method is the same as the cross-fire system used by Wickham and Degrais.

With radium and radium-emanation treatment the difficulty is also partly met, as has already been mentioned, by burying radium or radium emanation in the growth, or by varying the distance of the applied radium from the external skin. In the foregoing reference to the size and density of a tumour it has been more or less assumed that the tumour has been regular in outline and of uniform density throughout. But in practice, of course, malignant growths are of many and varied shapes, and they have near and distant secondary deposits; also they are by no means of uniform density, so that the problem of dosage becomes very complicated, and the most that can be hoped for is to obtain an approximation to what is desired which will work in practice.

*Delivered before the Southport Division of the British Medical Association.

The Position of a Tumour.

Its position has a very similar influence to the size and density of a tumour upon its susceptibility to radiations. If, for instance, it lies beneath or in tissues such as muscle and bone, it may become almost impossible to give it adequate radiations from the surface. If such factors as these are not present it may be possible that radiations from one side where the tumour is nearer may, at least in part, make up for deficiencies in radiation from the other side from which the tumour is farther away; but to get a proper quantity of rays traversing the growth many ports of entry may have to be used, and it becomes very difficult to get absolute accuracy of dosage. When cancers invade or are adherent to certain structures and organs such as bone, the stomach, bowel, liver, or lungs, treatment is rendered much more difficult, and often at the present time fails to produce a good result. It seems that not only is the nature of the tumour an important factor in ray treatment, but also the nature of the tissue and organs that it invades. The more accessible a growth is, as a rule, the better are the results, but growths of certain organs, such as the oesophagus, rectum, and tongue, seem to resist radium treatment more than elsewhere.

The consideration of the preservation of the skin is an ever-present problem to the radiologist. It has been already mentioned that under certain conditions it is possible that a stretched or ill-nourished skin may be more rapidly destroyed than a tumour, and, moreover, if the blood supply or ability of the skin to repair is bad, unless proper care is used the last condition may be worse than the first, from the formation of an intractable ulcer—not an x-ray or radium ulcer but a malignant one. That is to say, it may not be possible to give a suitable destructive dose to the ill-nourished tissues without risk. If one could be sure of destroying such a malignant growth beneath the skin there would be less difficulty in dealing with the factor of the skin, for it is almost certain that scar tissue would eventually form and fill up the gap; but the uncertainty of destroying the growth under these conditions makes the radiologist take more care in endeavouring to preserve the skin, and hence has arisen the so-called “erythema dose.” The burying of radium tubes will often, but not always, obviate this difficulty. In the case of rodent ulcers and epitheliomata of the skin not invading bone or cartilage, the skin, as a rule, has been modified or destroyed by the growth. In such cases the preservation of the epithelium need not be considered and marked local destruction produced if necessary, with knowledge that good repair will take place afterwards and a soft, supple scar be formed.

It will be seen from the foregoing remarks that the whole system of ray treatment is exceedingly complicated. The difficulties of dosage are modified by nearly all the usual things which may take place in a tumour from its nature or position. The possibility of actually stimulating an outlying portion of a growth which has been only partially radiated must always be borne in mind, although it is not as a rule a difficult problem in practice, because fortunately the range of dosage producing stimulation is an exceedingly small one.

What is needed is a large number of physical measurements of the different parts of the human body and of pathological growths, and a full and complete investigation of the nature of the lethal dose for cancer cells; when these have been made an approximate idea may be obtained of the method of treating tumours in different situations, although even then it seems that a number of impouderable biological problems, such as the resistance of the organism as a whole and the resistance of tissues locally to cancer growth, remain to be solved.

But in spite of all these difficulties, and the disadvantages in position in which radiologists are placed in this country of treating practically only inoperable cases, many good results are obtained from radium treatment: 7½ per cent. of all the cancer cases (mostly inoperable) which come to Manchester for radium treatment are alive and well to-day after periods varying from two to seven years, and many cases of carcinoma of the cervix of the uterus, breast, skin, lip, and other regions are in perfect health who would but for radium be dead; while endothelioma of the parotid gland and spindle-celled sarcomata show still more gratifying results. Moreover, short of cure much valuable palliative work is done, while in non-malignant conditions, such as exophthalmic goitre, Hodgkin's disease (when young), keloid, cavernous and capillary naevi, the percentage of cures is high; finally, radium is specific for excessive uterine hæmorrhage and spring catarrh.

THE SURGICAL TREATMENT OF CHRONIC ULCER OF THE BODY OF THE STOMACH.

BY

WILLIAM BILLINGTON, M.B., M.S. LOND., F.R.C.S.,

SENIOR SURGEON, QUEEN'S HOSPITAL, BIRMINGHAM.

THE surgical treatment of duodenal ulcer and pyloric ulcer can now be regarded as standardized and relied upon to give almost uniformly and permanently satisfactory results. Such a statement cannot yet be made in respect of ulcers situated in the body of the stomach. Their treatment has been difficult and disappointing, and the many and varied operative procedures advocated and practised have been gradually discarded as failing to give the results hoped for. Partial gastrectomy, involving excision of the segment in which the ulcer is situated, together with the portion of the stomach on the distal side of it, is strongly recommended by such eminent authorities as Sir Berkeley Moynihan and Mr. James Sherron as being the only method that can be relied upon to cure. On general grounds such a drastic remedy is only justifiable if we admit inability to succeed by simpler measures. The routine excision of an organ for a non-malignant lesion is at variance with the principles governing conservative surgical practice and is rather a confession of failure. That gastrectomy is advisable in certain cases of gastric ulcer may be admitted, but unless we are prepared to regard such ulcers as precursors of cancer its necessity in every case can only be accepted with great reserve. Further, even though partial gastrectomy is held to be the procedure of election the problem is not solved, for it is inapplicable in many of the worst cases of gastric ulcer and proves useless when most required.

For many years I was impressed by the uncertainty of the results that followed operations for gastric ulcer. Immediate and permanent relief of symptoms was obtained in some cases, while in others the results were only partially good or wholly unsatisfactory. Good or indifferent results bore no definite relationship to the size and character of the ulcer, nor to the particular operation performed. I tried posterior gastro-enterostomy with and without excision of the ulcer, excision of the ulcer without gastro-enterostomy, excision of the segment of the stomach in which the ulcer was situated by the “sleeve” method, and various other procedures that have been advocated from time to time. None of these methods gave uniformly good results, and it is of interest that my worst results occurred in a series of twenty-five cases in which small ulcers were excised freely and the opening carefully closed without the production of any appreciable deformity of the stomach. A very small proportion of these cases derived any benefit from the operation, and I have subsequently had to operate a second time upon nearly half of them.

Careful consideration of my cases gradually brought out the fact that the chief determining factor as regards result was the situation of the ulcer. My experience, which I believe to be in accord with that of surgeons generally, was that the relief of symptoms due to gastric ulcer becomes increasingly difficult the farther from the pylorus the ulcer is situated. The farther the ulcer from the pylorus the less satisfactory were the results obtained by the same operative procedure. There is no evidence that this is due to any essential difference in the morbid anatomy or the pathology of the ulcer. An ulcer in any part of the stomach is more or less subjected to the same physical conditions as regards chemical and mechanical irritation of gastric contents. If, then, there is a difference in the response of such ulcers to surgical treatment it can only be accounted for by variations of site and not of pathology, and treatment must be varied in accordance with that principle.

Following up the clue provided by clinical and operative experience, with the valuable assistance of Dr. Harold Black, radiographer to the Queen's Hospital, Birmingham, an endeavour was made to ascertain in what way an ulcer modifies the physiology of the stomach. That from a surgical standpoint any essential modification was in respect of its motility and not its chemistry I was convinced, and that the chemical part of gastric digestion could be modified by surgical operation to the advantage of the patient appeared highly improbable on general grounds, and my operative experience confirmed this opinion.

Radiography brought out clearly the fact that an ulcer of the stomach causes spasm of the segment in which it is

situated. This spasmodic contraction may last for a long time and be associated with considerable delay in the passage of the meal past the site of the ulcer. It was also observed that spasm of the segment in which the ulcer was situated was accompanied by feebleness or absence of peristalsis in the rest of the stomach. The x-ray observations went to prove that the effect of an ulcer, whether at the pylorus or in the body of the stomach, was the same. In both cases there is spasm of the ulcer segment and damping down of general peristalsis.

The immediate and lasting relief that follows posterior gastro-enterostomy for pyloric ulcer, and its failure in many instances to give the same result when the ulcer is situated in the body of the stomach, seems to depend upon the relationship between the site of the ulcer and that of the new stoma. In cases of pyloric ulcer the artificial stoma is always situated well to the proximal side of the ulcer, while in proportion as the distance of the ulcer from the pylorus increases the less likely is this to be the case if the ordinary rule is observed that the new opening should be made at the most dependent part of the stomach where the cardiac and pyloric portions join. When the ulcer is situated far over to the left it may well be that the new stoma lies wholly distal to it. This failure to modify the site of the stoma as the situation of the ulcer varies is, I am convinced, largely responsible for the varying results of gastro-enterostomy for ulcers of the body of the stomach. For relief of spasm it is essential that the new stoma should be placed well on the proximal side of the ulcer, and ulcer and stoma should bear a definite relationship to one another. Radiography demonstrates that when this is the case practically all the meal passes rapidly and smoothly through the new opening, little or none passing into the portion of stomach on the far side of the ulcer segment.

Clinical experience proves, however, that drainage of the stomach on the cardiac side of the ulcer only is not altogether satisfactory. The distal pouch is a factor that has to be reckoned with. It appears to become a "dead" cavity and a kind of cesspool in which stagnant stomach contents which have passed beyond the ulcer segment in small quantity collect. Peristalsis is feeble and ineffective to empty this pouch either by forcing back its contents into the proximal pouch or on through the pylorus. The result is that the patient experiences a sense of discomfort and epigastric fullness. To remedy this it is necessary to establish a second anastomosis between the distal pouch and the jejunum, or to extirpate the pouch altogether. That the latter is effective is certain, but that it is essential is open to criticism.

Briefly stated, in my opinion chronic ulcer of the body of the stomach should be treated as though an hour-glass contraction existed at the site of the ulcer. The alternative operations are: (1) Partial gastrectomy, the distal pouch, together with the ulcer, being removed and the proximal pouch anastomosed to the jejunum; or (2) double gastro-enterostomy, openings being established between the stomach and jejunum on either side of the ulcer. The choice between these two procedures is, to a large extent determined by the conditions found at the time of operation and by clinical evidence upon the question of malignancy.

For several years I have treated every case of chronic ulcer of the stomach off the above lines and have made no distinction between those cases in which definite hour-glass contraction existed and those in which it did not. At first I adopted partial gastrectomy as the procedure of choice, but in many cases, and those often the worst, it was impracticable. Where an extensive ulcer was adherent to the pancreas over a wide area or had penetrated through all the coats of the stomach into structures outside, gastrectomy would have been extremely difficult and dangerous. The same objection applied to cases in which the ulcer was situated far over to the left in the cardiac end of the stomach where closure of the proximal pouch could only be effected with considerable difficulty. Further, the general condition of some of the patients was such that it was undesirable to do more than was absolutely essential.

For these reasons it was often necessary to adopt the second alternative—that of drainage of the stomach on either side of the segment containing the ulcer. This is done by means of a single long opening or by two entirely separate anastomoses. The site of the ulcer is the sole determining factor, and so long as the openings are placed well to either side of it the most easily accessible portion of the stomach

wall is selected. Often it is impossible to utilize the posterior surface of the stomach for the anastomoses owing to dense adhesions, and the anterior wall is then selected. Owing to the necessity for placing the anastomoses in definite relationship to the site of the ulcer the usual technique for securing the smooth flow of bile and pancreatic secretion along the jejunum and the avoidance of regurgitant vomiting is rarely practicable. To obviate this risk entero-enterostomy is performed between the ascending and descending limbs of the coil of bowel taking part in the anastomoses. A loop of jejunum is taken, sufficiently long to allow of this lateral anastomosis being comfortably carried out. The whole operation involves a minimum of disturbance, causes a negligible amount of shock, and is easily completed in fifty minutes.

The results of the operation were surprisingly good, immediate relief being experienced. Indeed, so free from digestive disturbance were the patients that it was with the greatest difficulty that they could be persuaded to exercise the care with their diet that was obviously advisable for some months at least, in view of the fact that the unhealed ulcer still existed. That such care is necessary was shown by temporary relapse in several cases after gross indiscretions of diet. So good were the results that I began to extend the range of the operation, and to carry it out in preference to partial gastrectomy in cases in which the latter was practicable. I have now treated between fifty and sixty cases of ulcer of the body of the stomach in this way, and although many have been operated upon too recently to draw positive conclusions as to the permanency of the benefit obtained the general result has been very encouraging.

In discussing the choice between partial gastrectomy and double gastro-enterostomy with entero-enterostomy, the question of malignancy must be considered. If cancer often becomes ingrafted upon chronic gastric ulcer obviously the more drastic operation is preferable as more likely to remove this grave risk. The experience of English surgeons has been that ulcers which have existed for a considerable time rarely become malignant: that some ulcers are malignant from the onset is certain. Clinically it may be difficult to make a distinction, and I am accustomed to rely upon the duration and persistency of the symptoms. A short history with persistent and progressively severe symptoms is highly suspicious, while a long history with intermittency of the early symptoms makes primary malignant ulcer unlikely. The former history calls for gastrectomy, if at all possible, whatever the character of the ulcer at the time of operation. There is no reason, if the risk of secondary malignancy is feared and local conditions allow of it, why the ulcer should not be excised, or destroyed by the actual cautery as Balfour suggests, provided that the stomach on either side of its site is drained. Such local treatment is impracticable in the worst cases, and in the simpler ones I believe it to be unnecessary, the ulcer tending to heal rapidly, when efficiently short-circuited. It is remarkable how rarely at a second operation carried out some time afterwards there is any evidence of the original ulcer beyond some scarring of the stomach wall.

That double gastro-enterostomy with entero-enterostomy has a real value I am convinced. It can be relied upon to give prolonged relief in the worst forms of gastric ulceration where partial gastrectomy is contraindicated on account of the difficulty and danger involved. My experience of it has been too short to claim a permanent cure, but the maintenance of satisfactory digestion at the end of two years encourages the hope that it may prove to be so in many cases.

As to whether it should be regarded as an alternative to partial gastrectomy where the latter is practicable is more controversial. If equally good results are obtainable by the less severe operation, it must be the one chosen. Partial gastrectomy is, however, so strongly advocated by some very experienced surgeons that one is diffident about criticizing their statement that it should be the procedure of election. Before, however, accepting this view as applicable to all cases of simple ulcer of the body of the stomach, in which partial gastrectomy is possible, further evidence of its necessity must be forthcoming. Although in very experienced hands partial gastrectomy is not dangerous, it is a formidable operation for the ordinary surgeon and only justifiable if a cure is unobtainable by simpler, safer measures. For this reason I suggest a more extended trial of double gastro-enterostomy combined with entero-enterostomy.

SOME NOTES ON DEEP THERAPY.

BY

C. C. ANDERSON, M.B., Ch.B.N.Z.,

D.M.R. and E. LIVERPOOL,

X-RAY RESEARCH SCHOLAR IN CANCER AND RADIOLOGICAL REGISTRAR,
MANCHESTER ROYAL INFIRMARY.

It had become evident before the war that if radiotherapy was to progress on a scientific basis some accurate method of calibrating the output from the Roentgen tube must be found. Kienböck of Vienna had introduced a method depending on the action of the rays on an emulsion containing a silver salt, but it gave variable results in the hands of different and even the same workers, and it became evident that if it was to become generally useful the reason for these variations must be ascertained. Professor Wintz at Erlangen found that just as these silver salts are more susceptible to certain rays in the visible spectrum, so there are certain rays of definite wave-length in the x-ray spectrum which exercised a selective action on the silver salts ($\lambda = 0.055 - 0.049 \text{ \AA}$). This went a long way towards explaining the variations found, but did not overcome them. A step in advance was to measure the light given off by a screen containing platinum salts. Here the emulsion was protected from direct radiation by a heavy lead shield and only the light rays reached it. Though there were various objections to this apparatus, they were not so pronounced as in the case where the emulsion was acted upon directly by the x-rays. Another method was brought forward by two Frenchmen—Villard and Szilard—who made use of the property that x-rays have of ionizing air and so discharging an electroscope; they called their instrument the iontoquantimeter. The rate of discharge was given as directly proportional to the output of the tube. The original instrument was both cumbersome and inaccurate, especially in clinical use; it was considerably simplified and improved by Wintz and Banmeister of Erlangen, and has proved remarkably accurate; it has since practically displaced all other methods of measuring the output of different tubes.

This, though a great advance, was only a means to an end. Treatment had been directed more to the surface of the body, and deep effects had taken a long time to obtain. To obtain these effects more rapidly a ray was needed that would exert a minimum effect on the skin but a maximal effect in the depths of the body. It was necessary to eliminate all the softer rays which are arrested in the superficial layers of the body before they reached the skin. This was effected by increasing the amount of filtration; it was found that a zinc filter $1/2$ mm. thick gave the best result, especially when the time factor was taken into consideration. (This thickness corresponds to 11 mm. aluminium.) The next step was so to increase the output of the tube that the result was obtained in the shortest time. Apparatus could fairly easily be designed to give the required current, but it was some time before a tube was obtained which would stand up to the terrific strain of this continuous high voltage current. The tube evolved was the "self-hardening boiling water cooled tube."

Experiments to ascertain the optimum conditions under which the tube should be worked to give the best dose in the depths of the tissues showed that at the tension used a current varying between 1 and 2.5 ma. was the most satisfactory. Up to this time the condition of the tube had been regulated by an osmo-regulator controlled by the operator, but this method was found unsatisfactory because it allowed great variations in the condition of the tube. The automatic regenerator or regulator was therefore introduced by Wintz; in it the indicator of a current meter, introduced into the secondary circuit, impinging on a long lever, makes and breaks a current going to a solenoid, whose plunger acts as a valve in the tube supplying gas to heat the osmo-regulator.

The aim has been all along to decrease the time required for the treatment and to maintain the dose obtained in the depth of the tissues. A great advance has been made by using the Coolidge tube in conjunction with a special resistance, which has not only shortened the time necessary but actually increased the proportion obtained deep down.

On the Continent the difficulty of efficient insulation of coils has been solved, and transformers which give a varying output—up to 250,000 volts—for twelve hours daily without breaking down are in use. Both low and high output types of apparatus are available, but for malignant conditions a type with the comparatively low output of 2 to 2.5 ma.

seems the most favoured, for it allows the concentration of a number of small ports of entry upon growth, enabling the operator to obtain practically any desired dosage. Generally speaking, apparatus of a higher output requires the use of larger ports of entry, with a corresponding diminution in the total amount of radiation obtained in the depths of the tissues.

Methods of Application.

The methods of application may be considered under three headings:

1. Roentgen irradiation alone.
2. Roentgen combined with radium irradiation.
3. Roentgen irradiation combined with physical agents to increase the efficacy of the applied rays:
 - (a) electrolysis with metallic salts; (b) packing patient in paraffin blocks.

Methods 1 and 2 are in general vogue, though so far as I could ascertain for deep-seated tumours, especially of the rectum and the genito-urinary tract, the operators preferred to use radium to supplement the action of the Roentgen rays. This method, owing I think to insufficient screening, has unfortunately often been attended by unpleasant indurated scarring which sometimes leads to serious disability, and for this reason alone the use of radium has been practically abandoned in Erlangen, where it has been replaced by method 3 (a).

Not being altogether satisfied with results they attempted to increase the scattering—and hence the absorption—of the rays in the immediate neighbourhood of the tumour. It seemed that this could be accomplished most easily by the introduction of minute metallic particles in and around the tumour; it was found that one of the less irritating copper salts introduced by means of ionization was most suitable. Nothing has so far been published on this work; but at the Erlangen Frauenklinik it is claimed to be possible to bring about an even distribution of fine copper particles to a depth of 10 cm. The exact manner, however, in which it acts, whether by secondary radiation or by producing other effects, is still a matter of surmise; but the fact remains that, whatever the manner of working, the condition of the patient is very much improved, and at the present time the method is being employed wherever possible.

The most recent modification is that employed by Chaoul in Munich. Relying on the fact that actively proliferating cells are much more susceptible to radiations, he exhibits a dose to the whole body which is just sufficient to stimulate the cancerous cells to greatly increased activity. He follows this with a full dose some eight days later. He surrounds the patient with blocks of paraffin and delivers the main dose directly over the tumour. By means of the paraffin blocks much of the radiation passing outside the port of entry is caught and deflected back into the body, thus greatly increasing the amount of radiation received by the tumour. Chaoul states that as this method has been in use for only twelve months, it is too soon to draw conclusions, yet his results are very much better and he has had no untoward circumstances. The unit of dosage is in all cases measured by the production of an erythema within four to eight days; the interpretation of the term "erythema dose" varies with the different clinics, but in the end one comes to the conclusion that they agree on the whole about the amount of radiation required to treat the various tumours.

A point that strikes me rather forcibly is the insistence on the opinion that intensive therapy is not to be lightly undertaken, and then not without an extensive clinical examination, supplemented where necessary by the laboratory. Owing to the very real danger of "Roentgen cachexia" supervening, the patient's blood picture must conform to a very definite standard, and when below this, general tonic treatment is instituted in the endeavour to build up his health to this required standard.

The all-important question, however, is that of results. In the earlier results from 1914 onwards radiotherapy appears, on the whole, to be slightly more successful than operation, and there is no doubt that with the improvements in technique the indication is still more in favour of radiotherapy, even more so than of therapy combined with operative procedures. By results cure is not necessarily meant; that is almost impossible, I think, but we can speak of relief being more or less permanent. I do not think that the five years' standard is

* I am indebted to Dr. Langer—Professor Wintz's first assistant—for permission to make use of these notes, although nothing has been so far published on this work.

sufficient indication, because in many instances a relapse occurs between five and eight years.

In widely extended disease the tumour must be treated in two or more sections at intervals of six to eight weeks, and one of the most important effects I have noted is the great improvement in the condition of the patient which follows even the first application. This indeed is sometimes so marked as to be a return to work and entry, which is not so healthy as the surrounding integument, or else fancy themselves cured and fail to return at the appointed date, so that it is only months later, when the disease is often out of hand, that they come back expecting once more—often in vain—the relief they obtained from the first application. Again, not only is there almost entire absence of disability following irradiation, but in most cases where the relief is only temporary—as is also often the case after surgical procedures—the period of improvement is in nearly all instances longer than the surgeon could have given, and that without the considerable discomfort of an operation.

Classification of Results.

Results should be classified according to the method employed.

1. *Röntgen Therapy alone.*—As it is only within the last eighteen months to two years that this method has been successfully employed it is too early to speak of results, which, however, lose nothing by comparison with combined Röntgen and radium therapy data, and there is the added gain that with correct technique there is practically no risk of burning the patient.

2. *Röntgen Therapy together with Radium.*—In Germany the practice is to follow up the radium with Röntgen therapy. Two cases, treated in 1916, were seen in Erlangen; they were both peasant women, and looked as if they had never been ill in their lives. Two other cases seen in Munich, treated at a slightly shorter interval, were equally well. In Stockholm Professor Forssell reserves radium to administer the *coup de grace* following any exhibition of Röntgen rays.

3 (a). *Röntgen Therapy with Copper Electrolysis.*—This is proving the most satisfactory method of approach. There are some added dangers of burning the bowel owing to copper particles being excreted there; but the added benefits to the patient outweigh any disadvantages from this. It seems almost impossible to explain the reason for the great improvement in the condition of the patient, but there is no doubt about it. There is another advantage in that the scar resulting from this form of treatment is loose and supple, and in fungating conditions suppuration is lessened. This form of treatment is specially effective in malignant skin lesions which have resisted other forms of treatment, even including the application of radium.

One case I saw of a middle-aged man who had had an extensive ulcerative epitheliomatous growth of the skin overlying one scapula. He received the usual dose of x rays, which had not the slightest effect. After a period of eight weeks he was treated by copper ionization and again irradiated. Within a very short time an appreciable difference was noticeable, and the ulcerated area commenced to close in. This treatment was repeated after a further eight weeks and again after ten weeks. Within three months of the second treatment the lesion was healed and had remained so when seen two years later. Within the last few months, however, a recurrence took place in the middle of the scar, but this has been successfully treated again.

3 (b). *Röntgen Therapy and Packing with Paraffin Blocks.*—I was not able to see any results from this or even the apparatus in use, as the Surgical Clinic Röntgen Department was being rebuilt at the time of my visit; but despite its originator's claim and satisfaction, I think that a longer period than twelve months ought to elapse before any definite pronouncements can be made; but should it be successful it will lead to a very great simplification in the technique employed.

It is necessary to impress on workers the dangers as well as the benefits contingent upon the use of these newer methods. With the older methods there was very little if any danger of irritating a growth, but a carelessly focused application of the intensive rays may so stimulate an outlying portion of the growth that the patient soon succumbs to this rapidly growing portion.

Furthermore, the old days of haphazard application are gone—I hope for ever. It is no longer sufficient for the patient to come with a rough diagnosis and receive treatment; it is necessary that he should undergo an extensive clinical, laboratory, and if necessary radiological examination

—first, to ascertain the exact situation and extent, so far as is possible, of the tumour; and secondly, the condition of the patient and his fitness to undergo treatment. One of the most important examinations is that of the blood, which serves as the principal indicator of the state of the patient's health, and unless or until this conforms to a certain definite standard treatment cannot be safely undertaken.

The secret of success by these methods is intimate co-operation between clinician, pathologist, physicist, and radiologist; this necessarily means that it is a method which can and should be employed only in large hospitals where this co-operation can be easily obtained. The ideal is that there should be one large central institute in each of the greater cities where these conditions obtain.

Nothing could be worse than the action of some of the smaller hospitals—probably assured by those who do not know that there is no danger attending upon the use of this apparatus—in installing an intensive high-tension outfit, the working of which is positively dangerous in untrained hands. The technique should be employed only when a competent, properly qualified, and trained radiologist can be in attendance the whole time. It is absolutely essential that the greatest care should be taken that the rays are accurately focused, and this entails an accurate knowledge of anatomical relations that cannot be expected of even the best sister or lay assistant. This alone means that this technique should be on no account employed in cottage or even the smaller town hospitals, but only in central institutes in larger towns, as in the former case the radiologist at the best can be only a part-time officer, while the treatment, if justice is to be done it, must have at least one whole-time officer, who must not only personally make every focusing, but must also observe the patient from time to time in order to see that the rays are reaching the desired spot. Apart from the saving in capital outlay, by preventing unnecessary and wasteful duplication of apparatus, the prevention of the tremendous wastage of human life and happiness which would ensue through the inefficient and incorrect treatment that would necessarily obtain at the small local hospitals, is alone an overwhelming argument in favour of the large central institute, where the large number of cases seen and treated, together with the trained staff and opportunities for research and co-operation, conduce to a very much better end-result.

There cannot be the slightest doubt that intensive therapy is a great improvement on older methods, nor that it has come to stay; but it must be remembered, above all, that good and lasting results are only to be obtained by constant care and unremitting attention to detail. It is to be hoped, now that deep therapy is an established fact, that any improvements which follow will come rapidly and be along lines which will allow considerable simplification of detail. It is to be feared, however, that much of the deep therapy apparatus that is being installed in this country will not be properly used and that much discredit will fall on a method that is of very great help in relieving, if not in curing, the dread scourge of cancer.

THE RESULTS OF TREATMENT IN SYPHILIS OF THE CENTRAL NERVOUS SYSTEM.

BY

REGINALD HEARN, M.A., M.D. CANTAB.,

CLINICAL ASSISTANT TO THE LONDON LOCK HOSPITAL AND TO THE
WEST END HOSPITAL FOR NERVOUS DISEASES.

The following paper is a review of one hundred cases of syphilis of the central nervous system treated at the London Lock Hospital during the last two years. All the patients were men. Many more have been treated, but as a great number of these have been lost sight of, and many have been irregular in their attendance, it has been thought advisable to concentrate on one hundred cases only. Space prevents each case from being reviewed in detail, but it is hoped that the illustrative cases are sufficient to prove the main premisses of the writer. These are as follows:

1. A man is much more likely to develop nervous syphilis if his primary sore is of the papulo-erosive type. In the 100 cases under review 64 showed no trace of any scar, 33 showed the slight and almost invisible type of scar which

follows a papulo-erosive chancre when it leaves any scar at all, 2 showed scars typical of a papulo-ulcerative chancre, and in only one case did the scar prove that the original sore was a primary granulating chancre. One may therefore suggest that the smaller and the more transient the original sore the more likely is the patient to develop a nervous manifestation in later years. This no doubt explains why it is that so many patients suffering from obvious nervous syphilis are unable to give any history of an original infection.

2. Seventeen were of the meningeal, interstitial, or lato secondary type, and of these two were definite "neuro-recurrences" following salvarsan. In one case a facial paralysis appeared seven weeks after the last injection of neo-salvarsan, and fourteen weeks from the appearance of the sore, the treatment having consisted of 3.6 grams of neo-salvarsan administered in six weekly injections of 0.6 gram. The other case is described in detail later. Of the remaining 15 cases 10 had had no treatment worth mentioning, 3 had been well treated for nearly two years with injections of neo-salvarsan and mercury, and 2 had taken mercury internally—in one case for eighteen months and in the other for a year.

As the result of treatment all these patients were restored to normal health, so far as could be determined both by clinical and pathological means. There is, however, one exception to this statement. It was found that patients who complained of tinnitus aurium never lost this distressing symptom. The above good results only occurred provided the special treatment was followed up by an ordinary course of treatment for the syphilis. If this was neglected, the meningeal symptoms tended to recur and the cerebro-spinal fluid to become pathological again.

3. Degenerative or parenchymatous cases were materially benefited by treatment, so far as their subjective symptoms were concerned. Eighty-three cases were treated, but in no instance was it found possible to bring about any alteration in the physical signs, or to effect any permanent improvement in the pathological picture presented by the cerebro-spinal fluid. The question of treating this type of case was decided, not by the patient's physical signs but by his symptoms. If he complained of severe lightning pains, bladder trouble, or any other of the common symptoms of degenerative lesions, such as are met with in tabes or tabo-paresis, then it was found that the special treatment outlined below would almost certainly improve him. But if he complained of nothing, and the condition was discovered during examination, then it was found best to leave him alone.

4. The condition of the cerebro-spinal fluid was found to be of no value in deciding whether a patient suffering from degenerative neuro-syphilis should be treated. Four of the eighty-three cases were clinically typical tabetics, but the cerebro-spinal fluids were normal. All the same their subjective symptoms were greatly improved by treatment. It was found useless to gauge the efficiency of one's treatment by a progressive diminution in the cell count or in a reduction of the positivity of the Wassermann reaction. Broadly speaking, all the tests employed appeared to be uninfluenced by treatment. It is true that in two of the eighty-three cases the cell count came down to single figures, and in one the Wassermann reaction became negative, but this exception is not sufficient justification for assuming that the change wrought was necessarily the result of the treatment. It is too often forgotten that the tabetic lesion tends to come to a standstill, and in such cases the cerebro-spinal fluid may become normal once more.

5. In contradiction to the generally accepted view, general paresis were improved, and the onset of insanity postponed, provided that they were brought under treatment before they had become obviously stupid and fatuous. When the latter stage was reached treatment was worse than useless and only accelerated the fatal termination. Seven cases were treated in this series, of whom two were already stupid. These latter made no improvement: one is dead and the other in an asylum. But the other five are all holding their own, and three of them are certainly distinctly better. Their cerebro-spinal fluids, however, are just as pathological as on the day when they started treatment, and it may be mentioned in passing that when once the gold sol curve has assumed the paretic form it never changes again.

Rationale and Method of Treatment.

On the first day on which the patient was seen and a clinical diagnosis of nervous syphilis either made or suggested, the cerebro-spinal fluid was examined so as to

corroborate the pathological findings with what was noted on ordinary clinical examination. A week later the patient was given a maximum intravenous injection of one of the salvarsan substitutes, and, after a further interval of one week, the injection was repeated and immediately followed by drainage of the thecal canal. This method of alternate weekly injections and injections *plus* drainage was continued until the patient had received eight injections and four tapplings. In addition most patients received one or more intramuscular injections of intramino to intensify the action of the salvarsan substitutes, and to ward off metallic intoxication. The patient was then put on a potassium iodide mixture (with mercury as well if the case was "meningeal"), and the course repeated in two or three months' time if he felt no better, or if the symptoms returned. Provided that a suitable interval had elapsed since the termination of the last course, it was found that the patient's symptoms were the best indication as to when it was advisable to begin another.

The method outlined above was used in preference to the intrathecal injection of salvarsanized or mercurialized serum, for the following reasons. The treatment adopted is extremely simple, it causes the patient little or no distress, and it can be done with complete safety in the out-patient department or the consulting-room. The patient can get down from the table immediately the drainage is finished, and he is able to go about his ordinary business for the rest of the day. Headache was but rarely met with, and one might add that headache following lumbar puncture was found to be most infrequent when the cerebro-spinal fluid showed evidence of nervous syphilis, whereas it was almost the rule when the fluid was normal.

Recent researches¹ tend to show that the function of the cerebro-spinal fluid is to drain away rather than to supply, and that its withdrawal by lumbar puncture creates a negative pressure with a resulting ultra-filtration of substances from the blood. If, therefore, a drug is injected intravenously and the thecal canal drained immediately afterwards, the drug should be drawn more rapidly through the choroid plexuses on account of the negative pressure thus set up. Furthermore, if one accepts this view of the function of the cerebro-spinal fluid, the whole rationale of intraspinal medication falls to the ground, and one must conclude that the good results which do undoubtedly sometimes follow intrathecal injections of salvarsanized serum are due not to the injections but simply to the drainage. In this connexion the work of Barbat² is most striking. He showed that in 26 patients who were given an intravenous injection of neo-salvarsan and tapped immediately afterwards, it was possible, after twenty-four hours, to demonstrate 0.025 part of arsenic per 100,000 in the cerebro-spinal fluids of 23 of them. While, on the other hand, Rieger and Solomon³ showed that, if three hours were allowed to elapse after the injection, no arsenic could be detected in the cerebro-spinal fluid.

We can assume, then, that drugs injected intravenously do reach the cerebro-spinal fluid, provided that the injection is followed immediately by an auxiliary tapping. Finally, this treatment is absolutely harmless, while it was found that intraspinal injections of salvarsanized serum did in a few cases materially aggravate the lesions. It was because of this that Mr. McDonagh introduced the method now used at the Lock hospitals.

Illustrative Cases.

CASE I.

Male, aged 28. This was a true "neuro-recurrence." He developed a "neuro-recurrence" in the coronal sulcus in April, 1919, and was treated with injections of neo-salvarsan and a course of mercurial. In October, 1919, he first noticed headache which was worse at night—this was nearly ten weeks after his last injection of neo-salvarsan. When seen in December, 1919, he complained also of deafness, tinnitus aurium, and occasional attacks of giddiness. On examination both the vestibular and cochlear portions of the auditory nerve were found to be affected; there was obvious deafness. Furthermore, nystagmus was present, and the water and rotary tests for vestibular nerve involvement were positive. His course of treatment extended from December 9th, 1919, to the end of February, 1920. On December 9th an examination of the cerebro-spinal fluid gave the following result (a normal result is shown for comparison):

	Patient's	Normal
	C.-S. F.	Result
Cells	120	1 to 5
Globulin	++	—
Wassermann reaction	++	—
Gold sol	000112553	000000000

Examination on December 23rd showed: Cells 210, globulin and Wassermann tests positive, gold sol 000112253.

From this time onwards the findings became less pathological, and when the cerebro-spinal fluid was examined at the end of February, 1920, it was found to be perfectly normal.

This, of course, was a case of meningitis with involvement of both vestibular and cochlear branches of the auditory nerve. From the first drainage the physical signs improved enormously, and, when examined fourteen days after the last, the headache, deafness, and nystagmus had entirely disappeared. The tinnitus aurium, however, persisted, as always happens in this type of case. The rise in the cell count after the first tapping is worth noting, as it was almost a constant phenomenon, especially in cases of meningitis.

CASE II.

A man, aged 34, developed a papulo-erosive chancre on the frenum in 1917. When seen in February, 1920, he complained of intolerable headache and almost complete loss of memory for recent events. He had had two epileptic fits in the previous month. Clinical examination revealed nothing abnormal except that the deep reflexes were rather exaggerated. His cerebro-spinal fluid was examined on February 2nd and 3rd, 1920, and again on March 27th, 1921. The results are shown in the following table:

	Feb. 2, 1920.	Feb. 23, 1920.	Mar. 27, 1921.
Cells	100	254	3
Globulin	+	doubtful	—
Wassermann	++	doubtful	—
Gold sol	00123444	01133211	00000000

Treatment extended from February 2nd to April 27th, 1920. The patient's symptoms rapidly cleared up. He continued on mercury and potassium iodide, and, when seen a year later, looked in robust health. He complained of nothing, and had had no more fits. His cerebro-spinal fluid was again examined and, as will be seen by the table, was found to be perfectly normal.

CASE III.

A man, aged 50, developed a papulo-erosive chancre on the glans penis in 1891. He was treated with mercury for four months after infection, but had had no treatment since. When seen on September 20th, 1921, he stated that he had suffered from lightning pains in his legs for the last eighteen years, and from urinary incontinence for over five years. His physical signs were those typical of a case of tabes, and in addition he wore a portable urinal. An examination of cerebro-spinal fluid on September 20th, 1921, gave the following results: Cells 22, globulin test positive, Wassermann reaction strongly positive, gold sol 012441000.

Treatment was at once instituted, and, although it is now only two months since it was started, the patient's general condition has already vastly improved. The lightning pains have entirely disappeared, and, although he still has some frequency of micturition, his bladder trouble is very much better, and he has given up his portable urinal. There is no alteration, however, in the cerebro-spinal fluid picture, and when this was examined on November 16th, 1921, it was practically the same as on September 20th. He still, of course, shows the same physical signs as before, but from his point of view his life is now worth living, and he can pass water almost like a normal man instead of having to let it dribble into a urinal all day long.

CASE IV.

A man, aged 46, developed a papulo-erosive chancre on the glans penis in 1901, and was treated with mercury for eighteen months. When seen on April 6th, 1921, he showed the usual physical signs of tabes plus a greatly enlarged Charcot's left knee-joint, which had appeared after a kick from a horse in France in 1917, and for which he wore a special walking apparatus. He complained of lightning pains and headache, and could not exactly remember when they started. His first course of treatment extended from April 6th to June 1st, 1921. His cerebro-spinal fluid was examined on both of these dates, with the following results:

	April 6.	June 1.
Cells	67	36
Globulin	+	+
Wassermann reaction	++	++
Gold sol	234455210	122211100

By this time the lightning pains had greatly improved, but the most interesting thing of all was that the Charcot joint was now half its former size, the whole of the redundant synovial fluid having been absorbed. The expensive apparatus which he was wearing was now much too big for him, and he had to discard it. In August, 1921, he began to suffer from headaches again, so he was given a further course of treatment, which resulted in the disappearance of this symptom. At the present time he is free from symptoms, and the effusion in the Charcot's joint has not recurred. His cerebro-spinal fluid picture is still much the same as when treatment was first started.

CASE V.

A man, aged 36, developed a papulo-erosive chancre on the coronal sulcus in 1911, and was treated in Italy for three and a half years with weekly intramuscular injections of mercury (with occasional rests) and potassium iodide by the mouth. He remained perfectly well until the beginning of 1920. At this time he began to neglect his work, and his friends and relatives noticed that he was getting slovenly and neglectful in his habits and appearance. These symptoms gradually progressed, and he was given a long holiday by his firm with instructions to "pull himself together." On June 29th, 1920, he presented himself at hospital. He talked volubly with a markedly slurring speech, the tendon reflexes were

exaggerated, and the pupils sluggish and irregular. It seemed obvious that he had developed general paralysis, and this opinion was confirmed by an examination of the cerebro-spinal fluid, which gave the following result: Cells 55, globulin and Wassermann tests both strongly positive, gold sol 55555554342.

He was treated from June 29th to August 10th, 1920, with the result that his mental condition considerably improved. He was given another course in November and December, 1920, and it is worth noting that the pathological picture of his cerebro-spinal fluid on December 1st, 1920, was: Cells 50, globulin test positive, Wassermann reaction strongly positive, gold sol 5555554433.

By March, 1921, his general condition had improved so much that he returned to his work. During 1921 he has received two courses of special treatment. His speech is still slurred, but his mental condition is good. He finds no trouble with his work, and appears rational and intelligent. The last examination of his cerebro-spinal fluid was on November 29th, 1921, and the result was as follows: Cells 22, globulin and Wassermann tests both strongly positive, gold sol 5555555221. One can therefore say that a considerable part of the insane has for the the cerebro-spinal fluid of that condition.

The cases were all under the care of Mr. McDonagh, and my thanks are due to him for his kindness in allowing me to make use of them, and for his unfailing help and resourcefulness when difficulties were encountered. Without his co-operation the work could not have been done. Furthermore, I cannot conclude this survey without stating that I have merely carried on the work which was begun by the late Dr. Lawrence Shaw, and which was cut short by his untimely death in March, 1921. To him, therefore, belongs much of the credit for the good results obtained. The pathological work was done by Mr. Victor Corbett, and to him also I express my thanks.

THE TREATMENT AND PROGNOSIS OF LEPROSY.*

BY

P. HARPER, M.R.C.S., L.R.C.P.,

MEDICAL SUPERINTENDENT, MAKOGAI LEPER ASYLUM, FIJI

Of the general measures that can be taken for the benefit of lepers the following are essential:

(a) Regular meals of abundant food, including plenty of milk. Unfortunately I do not know what is the diet of the majority of patients at Makogai. I only know what the Government ration is, and that is certainly not the complete diet of the patients.

(b) A literally open-air life. At Makogai the wards, open-air as they are, are used merely as dormitories, the patients spending practically all their time in the shade of trees, or in shelters or in their gardens.

(c) Gentle exercise and daily baths. The latter are very important from the ease with which lepers get small wounds. If the skin is clean there is not much harm from them, but if the skin is dirty they may form the starting point of very serious infection.

(d) Happiness of mind, obtained by kindly personal interest, plenty of amusement, and remunerative work. There should be as little petty discipline and interference as possible, and there should be no talk nor hint, whether by staff, patients, or visitors, of the loathsomeness or incurability of the disease.

Leprosy is not incurable, nor is it nearly as loathsome as many other diseases. But though we disapprove, we must still recognize and allow for the stigma that is attached to leprosy, a stigma due in part to the rareness of the disease in civilized countries with a corresponding ignorance on the part of the general public. This stigma will, of course, soon pass away, just as the horror with which sleeping sickness was regarded twenty years ago has disappeared with the increase of knowledge. One can have nothing but praise for the humane campaign of the Hawaiian leprologists for the true education of the public and the consequent eradication of this mediaeval stigma. Leprosy is a disease of such low infectivity that it appears to me to be the ideal disease for treatment at the patient's home. I do not agree that complete compulsory segregation will ever succeed in wiping the disease out of Fiji, whereas segregation at home or in an

* A paper read at a meeting of the Fiji Branch of the British Medical Association, May, 1922.

asylum in the patient's own district (say, in an annexe to the provincial hospitals) might be much more successful.

There is a wide field for simple surgical measures, especially in the septic infections that are so troublesome. Perforating ulcers, often situated superficial to very chronic adventitious bursae, are best treated by excision with the bursae. Rhinitis, iritis, and neuritis are, after sepsis, perhaps the commonest symptoms calling for treatment. Often the intractable uveitis is enormously improved by cutting down on the nerve in the whole length of the enlarged portion and peeling the epineurium from the inflamed nerve. The wound is closed and the relief is immediate. The rhinitis, especially if very fetid, is much improved by irrigation twice daily and packing with sterilized gauze. Leprous iritis must be treated in the same way as iritis from other causes. Septic ulcers heal with remarkable rapidity if they are carefully tended, as is the case at Makogai, where our sisters and dressers perform an average of one hundred and fifty dressings daily.

Specific Treatment.

I have tried, amongst others, the following specific treatments:

(1) By the intravenous injection of tartar emetic. Although two cases were given 43 grains in thirty-five injections and 46 grains in thirty-seven injections respectively, there was no improvement which could be attributed to the tartar emetic. Therefore I regard this treatment as useless for leprosy.

(2) By the intramuscular injection of ethyl esters of chaulmoogra oil. This method is expensive and very painful, and is not as effective as methods 3 and 5 detailed below. I am now trying this drug intravenously. It is well borne, but I have not yet experience enough to give an opinion as to its value.

(3) By intravenous and oral administration of sodium hydnocarpate. This is also an expensive method. It is not as effective as method 5 detailed below, but if one misses the vein and gives the drug subcutaneously the resulting swelling is not so painful as in the case of the oil and is more rapidly absorbed.

(4) By the intramuscular injection of chaulmoogra oil in various mixtures, chiefly according to Heiser's formula. This is painful, and the injections cause a fibrous degeneration of the muscles. Further, there is no knowing how much is absorbed, for months after the injection the oil may be aspirated unchanged from the injection site. Nevertheless, this treatment is valuable and the patients do well on it.

(5) By the intravenous injection of crude chaulmoogra oil. A good average specimen of chaulmoogra oil at room temperature in Fiji consists of about equal parts of solid and liquid constituents. This is sterilized by heat. From 5 to 15 minims of the oil at body temperature are injected once, twice, or three times daily. My present plan is to give a fortnight's rest at the end of each four weeks' injections. The treatment is maintained until a "treatment reaction" occurs, when it is stopped until the reaction is over. I used to give the oil intravenously in a mixture with ether and iodine, or carbolic, but find the crude oil as above to be more satisfactory. During the last two years 35,000 intravenous injections of chaulmoogra oil have been given at Makogai. Syphilis, compensated heart diseases, tuberculosis, and the filarial diseases are not necessarily contraindications. Cases of albuminuria without casts have lost their albuminuria during treatment with this method. Chaulmoogra oil was first given intravenously by Varham, Stenel, and Noc. They gave it in fine emulsion; but their doses were very small, being about one-hundredth to one-fortieth of the doses given by me. Nevertheless they obtained good results.

Chaulmoogra oil is so unpleasant to take by the mouth or subcutaneously that for years efforts have been made to find an unirritating active principle. One of the earliest of these was "antileprol," rediscovered recently and much praised as the ethyl esters or "Dean derivatives" by the Hawaiian leprologists. Another rediscovery is Sir Leonard Rogers's sodium hydnocarpate and gyuocardate, the sodium salts of hydnocarpic and gynocardic acids, which were used twenty years ago by Roux.

These derivatives of chaulmoogra oil seem to act in the same way as the oil itself, over which they have no real advantage. Their action is not, I think, due to the purely antiseptic action of the oil, which is stated to be selective for the acid-fast group. Injections of chaulmoogra oil cause a transient leucocytosis which might repay investigation. Whatever the mode of action may be, there is no doubt that

chaulmoogra oil taken over long periods does ameliorate most cases of leprosy and cure some. After weeks or months of treatment a stationary case will have a "treatment reaction," evidenced by fever, eruption, and neuritis, hardly if at all to be distinguished during the fastigium from true leprotic fever. After the subsidence of the symptoms, however, a definite change for the better takes place. Treatment must be carried on for years.

Prognosis.

In early and mild cases there is a fair hope of cure or arrest of the disease. In pure nerve leprosy arrest of the disease has already taken place in a large number of the cases admitted to Makogai. I can see no justification for the segregation of these patients, many of whom are not capable of transmitting the infection at the time they are signed up. Yet if such a patient is admitted to the asylum the law requires that he remain segregated for a minimum of two years.

Advanced nodular cases or cases with marked nerve deformity are comparable to cases of generalized tuberculosis and cases of fibrous phthisis respectively, for in the one set of cases the body is little more than a culture medium for the bacilli, whilst in the other the disease, although it may have ceased to be active and infective, has caused immense loss of tissue and deformity. Such cases are, to use the layman's language, incurable.

In many cases leprosy actually prolongs life, for if a man contracts the disease he orders his life sanely with the idea of combating not merely his leprosy but also the possibility of other diseases and vices. I can give no figures for the length of life after infection, but from modern researches, especially those of Sir Leonard Rogers, it appears that in the vast majority of cases infection takes place during the first few years of life. Yet the majority of our cases die at an advanced age.

Lepers do not as a rule die of leprosy. The causes of death in the first 157 deaths at Makogai are as follows:

Tuberculosis 42, septic infection 31, nephritis 18, leprosy 14, exhaustion 5, undetermined 5, tetanus 4, senility 3, pneumonia 3, dysentery 3, suicide 3, amyloid disease 2, malignant disease 2, filariasis 2, peritonitis 2, influenza 2, mitral disease 1, angina pectoris 1, pulmonary embolus 1, cerebral tumour 1, duodenal ulcer 1, intestinal ulceration 1, bronchitis 1, renal abscess 1, general paralysis of the insane 1, epilepsy 1, hemiplegia 1, pharyngeal ulceration 1, diabetes 1, syphilis 1, anæsthesia 1, fatty heart 1.

From the above it is seen that tuberculosis and sepsis are the chief causes of death. The prognosis in civilized races is far and away better than in lower races. Osler, for instance, records the case of a clergyman performing his duties for thirty years whilst a leper, though none of his flock knew of his disease. Similar cases of lepers, unsuspected by the general public, living active beneficent lives, occur in most of the countries in which the disease is endemic, including Fiji.

A SIMPLE PORTABLE APPARATUS FOR CONTINUOUS OXYGEN ADMINISTRATION.

BY

GEOFFREY BOURNE, M.D.,

PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN, CHIEF ASSISTANT TO A MEDICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL.

For many years oxygen has been largely used in the treatment of pneumonia, but generally it is given sporadically and rather with the idea of meeting some crisis in the patient's condition. Its use as a continuous therapeutic agent came under the writer's especial consideration in the treatment of severe cases of bronchopneumonia, complicating pertussis and measles, in the wards of the infectious block of the East London Hospital for Children. Dyspnoea and cyanosis were of course predominant symptoms in many cases, and the lack of proper oxygenation of the blood appeared to be a serious, often a fatal, handicap to recovery. Physiological, pathological, and chemical work upon the oxygenation of the blood also point in the direction hinted at by these clinical signs. Pneumonia is certainly a condition in which there is often anoxæmia; the place of oxygen in its treatment should therefore be one rather of regular use than of spasmodic effort. The same is true of other conditions complicated by lack of oxygen, such as chronic bronchitis and emphysema, asthma, and many types of heart

disease. In the cases of bronchiopneumonia above referred to oxygen was given at first by the usual funnel method. This, however, suffers from many disadvantages: the presence of a nurse is necessary; much oxygen is wasted owing to rapid diffusibility; it is doubtful whether the inspired air has a much raised oxygen tension; and the presence of a large funnel in close proximity to the face is often resented by a restless patient. These are all difficulties which it is essential to overcome in the production of an apparatus which will usefully administer oxygen. An oxygen chamber is, of course, ideal, for the oxygen tension can be exactly regulated. It is a luxury, however, which is restricted to a few institutions of sufficient wealth, and even in them it can only be used in a small proportion of cases, so that the lesser hospitals and the private practitioner must look elsewhere.

Description of Apparatus.

The diagram is nearly sufficiently explanatory of the apparatus which forms the subject of the present communication. A webbing or elastic circle, whose size can be regulated by a buckle, grips the head firmly but not tightly. On the front of this is an aluminium plate, A, which acts as a firm base for the brass pin B. Through a vertical hole in this passes an aluminium rod, C, which can be fixed at any level by a screw. Loops at the extremities of this hold a rubber catheter (size 6), D; they grip it but allow it to be pulled through to any desired length. Oxygen passes from the cylinder through a Wolff's bottle containing fluid (water or brandy) and standing in a bowl holding warm water. From this it passes to the patient, who receives it intranasally through the rubber catheter.

Method of Use.

Attention to a few details is necessary when fitting the apparatus to a patient. The catheter must first be lubricated, and the best ointment for this has been found to be novocain 2 per cent. in vaseline; it should be inserted to the level of the posterior nares, or a little beyond, but must not touch the posterior pharyngeal wall. If a thread be tied round the catheter to mark the depth to which it is desired to introduce this, a nurse can easily see whether any slipping has occurred and can quickly and accurately readjust it. The lower loop in the aluminium wire should be as near the nostril as possible. The rubber tube to which the catheter is attached can be suspended, in which case the movements of the patient's head are quite unrestricted. The rate of flow of oxygen can be seen by the rapidity of the bubbles through the brandy or the water in the Wolff's bottle, and the speed need be no faster than about 70 to 80 bubbles a minute. Oxygenation is efficient at a much slower rate of flow than with an open funnel.

Mechanical Advantages.

The apparatus is a stable one. Since it moves with each movement of the head the patient is not worried, and soon becomes reconciled to it, eventually forgetting its presence. It is very light and portable. Oxygen is conducted to a position whence much of it is inspired; there is thus actually a very considerable saving in the amount of oxygen used. It is inexpensive.

Clinical Advantages.

It has been used in twenty-three cases of severe bronchiopneumonia in children. Cyanosis is not seen in cases using it. Sleep is not interfered with. There is no increase in the number of paroxysms in cases of bronchiopneumonia in pertussis; there is thus no local irritation from its presence. Other signs of irritation or resentment are not seen, as a rule, although occasionally it has been found necessary to tie the hands down. Oxygen can be given continuously and indefinitely in an effective and economical manner.

There appears to be no reason why its use should be restricted to children; they provide the more searching test, and success with them should promise at least an equal success in adult cases. It should prove of use in any pulmonary or cardiac condition complicated by anaemia and cyanosis. The instrument is made by Messrs. Maw, Son and Sons, of Aldersgate Street, who have agreed that all profits from its sale should go to the East London Hospital for Children.

TREATMENT OF PSORIASIS BY MANGANESE.

BY
JAMES MOORE, F.R.C.S. EDIN.,
BELFAST.

THE only specific treatment of psoriasis, up to the present, is the external use of chrysophanic ointment. Arsenic is useful in anæmic cases, sodium salicylate in cases with a rheumatic history, and thyroid extract in the obese or those with symptoms of hypothyroidism. These improve the disease by improving the patient's general health, but have no specific action.

In the autumn of 1920 I had under treatment two cases of chronic staphylococcal infection, who at the same time suffered from well-marked psoriasis. After six injections of gradually increasing doses of staphylococcal vaccine, my patient informed me that the skin was better than it had been for years. I continued the vaccine for another six injections, but with no appreciable improvement in the psoriasis.

The well-known benefit derived from the use of intramuscular injections of collosol manganese in staphylococcal infections, also the fact that collosol manganese, like staphylococcus vaccine, will bring about an acute recrudescence of streptococcal eczema, suggested its use to me in these two cases. The results were very satisfactory: one was cleared up completely after four injections, and the other after eight.

I have treated in all 35 cases of psoriasis in the past twenty months, of which the following is typical of the procedure adopted.

C., a strong healthy man, aged 43. Sixteen years ago a spot of psoriasis, the size of a sixpence, appeared on left leg, two inches above the external malleolus. In six months the disease had spread to the knee, and entirely surrounded the leg. After three years the other (right) leg was attacked in a similar manner. Six years ago the disease appeared in the lumbar region, and extended on the back as high as the scapula. At the same time both elbows became affected, and it extended on both arms almost to the wrist-joint on the extensor surfaces. About six months before consulting me a patch about four inches square appeared in the right inguinal region.

Such was his condition when he consulted me on January 6th, 1922. With the usual antiseptic precautions, I injected into the deltoid muscle (left arm) 1/2 c.cm. collosol manganese (1/4 c.cm. No. 1 sol., 1/4 c.cm. No. 2 sol. (Crookes), mixed in syringe) and ordered him to use vaseline to assist in removal of the scales, and allay the irritation. On January 10th 1/2 c.cm. collosol manganese was injected into the right deltoid; on the 17th 1 c.cm. into the left deltoid; on the 24th 1 c.cm. into the right deltoid; and on the 31st 1 c.cm. into the left deltoid. On this last date the inguinal patch had almost disappeared, and on the back and elbows islets of healthy skin were showing in the centre of patches.

On February 7th 1 c.cm. collosol manganese was again injected; the improvement continued. On February 14th a further 1 c.cm. was injected. On this date, with the exception of a small patch about two inches square, the disease had entirely vanished. I continued the weekly injections of 1 c.cm. collosol manganese up to the end of March, when the patient was completely cleared. In all the patient received thirteen injections. Vaseline was the external treatment.

From my study of psoriasis and its treatment by collosol manganese I have arrived at the following conclusions:

1. The clinical appearance and behaviour of psoriasis suggest a spirochaetal origin, but neither salvarsan, its congeners, nor mercury have any beneficial effect on the disease.
2. Mixed staphylococcal vaccine will improve the lesions, but will not bring about their complete disappearance, without the use of chrysophanic ointment.
3. Collosol manganese will clear up the disease in from six to sixteen intramuscular injections without the assistance of any external treatment. I prescribe vaseline where there is much irritation.
4. From the action of staphylococcal vaccine, and especially collosol manganese, I would suggest that psoriasis is probably due to a special staphylococcus, or at least bears an intimate relationship to chronic staphylococcal infection.
5. The disease is, in my opinion, auto-inoculable.
6. A number of cases in the same family can be accounted for by living under the same conditions, and subject to the same infection, rather than by heredity.

ZINC IONIZATION AS A DISINFECTANT IN LOCAL SEPSIS ILLUSTRATED BY ITS USE IN CHRONIC OTORRHOEA IN CHILDREN.

BY

A. R. FRIEL, M.D., F.R.C.S.I.,

AURAL SPECIALIST, MINISTRY OF PENSIONS BOARDS.

THE proof that zinc ionization is an effective treatment for surface or open septic lesions such as chronic otorrhea, abscesses in various parts of the body, ulcers, endometritis, pyorrhea, impetigo, etc., rests on considerations drawn from physics regarding the electrical current, the action of the zinc ion on albumin, the situation of the micro-organisms in the diseases in question, etc.; on laboratory experiments, designed to show that albuminous fluids as well as tissues can be sterilized by zinc ionization; and on clinical results. We owe its use to Professor Leduc.

In the last resort we found our judgement of the applicability of any method of treatment on the clinical results, but often it is difficult, on account of the complexity of conditions in disease, to present them in a convincing form. When we endeavour to do so it is desirable that we should specify the actual factor of the disease which we treat, and what is the actual effect of the remedy. If the disease in question presents one factor alone, or one factor preponderating greatly in its action over other factors, and if the remedy has only one action, or one action preponderating greatly over any other effect, we have a reasonable basis on which to form a judgement. The main factor in maintaining the otorrhea is septic fluid in the ear. Zinc ionization is an efficient method of sterilizing an infected cavity.

When we are presented with a case of this disease we ask ourselves whether (1) the whole of the septic area is accessible; whether (2) there is any other factor present which would make it not worth while to sterilize the cavity; and whether (3) there is any condition in the patient which would lead to speedy reinfection.

If the sepsis is confined to the tympanum, and does not involve the attic or mastoid, and the perforation in the drum is large enough to allow fluid, such as zinc solution, to enter the ear, treatment by zinc ionization results in rapid and complete cessation of the discharge; this result is consistently obtained.

If besides sepsis another factor is present maintaining the otorrhea, such as the irritation of a polypus or the exudation from large granulations, it is not worth while to attempt to sterilize the ear until the polypus is removed or the granulations have been treated. In these cases our first duty is to convert the complicated condition into the simple one of tympanic sepsis.

Under the third heading we may note that if the patient has inflamed tonsils, inflamed adenoids, purulent rhinitis or sinusitis, or pyorrhea, we cannot expect the otorrhea to cease until the infecting condition is removed.

Subjoined is an analysis of the cases showing the cause of chronicity and the results of treatment.

The clinical results obtained in cases of tympanic sepsis afford evidence of the efficacy of zinc ionization as a disinfectant suitable for applying to exposed tissues, or to mucous surfaces, as in addition to the results being rapidly, completely, and consistently obtained, the remedy (zinc ionization) is the sole or essential part of the treatment adopted.

The only treatment for tympanic sepsis employed at the ionization clinics is zinc ionization with or without the insufflation of boracic acid. In very slight cases the insufflation of boracic acid without ionization is adopted.

A word must be said about consistency. This implies similar, or identical, treatment in similar conditions. It is easy to use the same ionizing solution, but it is not possible to give each area of successive tympanic cavities an absolutely identical dose, as one tympanum may be larger than another and it is not possible to compare the size of each exactly. Again, with regard to similar conditions in successive patients: in one ear there may be a good deal of swelling of the tissues and in a second little, but with these provisos there is approximately similar treatment in similar conditions.

Of the 102 cases considered to be due to tympanic sepsis 83 were known to be cured, 14 were lost sight of, and 5 were still under treatment; 7 of the 14 only visited the clinic once, and 3 of the 5 had only made one visit. In none of the other

Cases of Otorrhea in Children.

Classification of the "Cause of Chronicity" in each Case.	Total.	Cured.	Lost sight of.	Still under Treatment.	Referred for operation or other treatment.
A. CHRONIC MIDDLE-EAR SUPPURATION.					
I. Treated by Ionization.					
1. Tympanic conditions:					
Tympanic sepsis	102	83	14	5	0
Tympanic sepsis + granulations ...	40	23	6	9	2
Tympanic sepsis + polyp	19	5	3	5	6
Tympanic sepsis + cholesteatoma ...	3	1		2	
in tympanum					
Tympanic sepsis + pocket formed by adhesion	1		1		
Tympanic sepsis + caries of malleus	1		1		
2. Tympanic conditions + involvement of the Eustachian tube, pharynx, or nose	10	3	3	2	2
3. Tympanic conditions + involvement of the mastoid:					
(a) Mastoid	59	9	6	8	36
(b) Attic	15		2	5	8
(c) Radical (operation already)	1		1		
(d) Operation already (not radical)	5	2	1	1	1
4. Tympanic conditions + cause undetermined	3		1	1	1
5. Tympanic conditions + external otitis	5	5			
II. Not Treated by Ionization.					
Tympanic sepsis	264	131	39	38	56
Tympanic sepsis + granulations ...	18	16	2		
Tympanic sepsis + polyp	1			1	
Tympanic sepsis + external otitis ...	8		1	1	6
Tympanic sepsis + mastoid	1	1			
Tympanic sepsis + radical mastoid cavity	1			1	1
	7	1	0	1	5
B. EXTERNAL OTITIS.					
I. Treated by ionization	36	18	3	3	12
II. Not treated by ionization	3	3			
C. ACUTE OTITIS MEDIA.					
Not treated by ionization	7	7			
Totals	307	156	42	41	68

7 lost sight of or the other 2 still under treatment had the attendance at the clinic been of long duration. Of the 83 cases which were known to be cured 53 were cured with one treatment, and 12 more required only the insufflation of boracic acid on the second visit a week after the first treatment. The remainder required either a few more ionizations or insufflations of boracic acid, or both.

The remainder of the table represents (1) cases in which attempts were made by special apparatus to introduce the zinc solution into areas more or less inaccessible, such as the mastoid antrum or a mastoid cell; (2) cases in which an effort was made to reduce a complicated condition to a simple one; and (3) cases in which it was necessary to free the patient of a condition which would lead to reinfection, such as inflamed adenoids, or inflamed tonsils, or an inflamed external auditory meatus.

In all the cases of chronic otorrhea sepsis is the basic factor causing chronicity; it is for sepsis that the use of zinc ionization is desirable. Zinc ionization is, in my opinion, as a result of what I have seen and read, the remedy *par excellence* for the septic factor present in endometritis, abscesses, boils, pyorrhea, or accessible wounds. It should, I believe, be adopted in sepsis of the uterine cavity following infection in childbirth.

In treating the various conditions mentioned the doctor who intends to use this form of treatment should give the treatment himself. He alone knows the local condition, he alone has the requisite knowledge of the condition in his patient. The electrical knowledge requisite to practise ionization is easily acquired. The knowledge of the conditions in the patient takes much trouble to learn, and the only person who has a chance of gaining this knowledge is the person who is in charge of the case.

ACCORDING to a report received from the Health Section of the League of Nations there is a serious increase in the incidence of cholera in the Ukraine. During the last three days of May 360 new patients suffering from cholera were admitted into the Odessa hospitals, where 1,000 cholera cases were under treatment.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

INFECTIVITY OF ARTIFICIAL DENTURES.

As an early and enthusiastic upholder of the opinion that dental decay is frequently the cause of a sepsis resulting in arthritis and periartritic inflammations, as well as other inflammatory manifestations, may I draw more attention than is at present given to the fact that artificial dentures are also a cause of many inflammatory affections of the throat and intestinal tract? I would even go farther and say that they may be indirectly, if not directly, the cause of joint affections also. Having found out that a person is edentulous one is rather apt to pass on to other fields of inquiry, but it is well to inspect the dentures, for there is a good deal to be learnt from doing so; the mouth also should be inspected and all the more carefully if the throat seems somewhat inflamed. A stump of a tooth may be found—I have recently found in two elderly people who had arthritis a recently erupted wisdom tooth decayed. A decayed tooth amongst sound ones is bad enough, but under an artificial denture it is ten times worse. Apart, however, from the presence of a bad tooth, I am quite certain that dentures are far more frequently than is generally recognized the cause of pharyngeal catarrh and intestinal troubles, the latter being often erroneously put down to the patient not chewing food sufficiently, whereas it is really due to the infective nature of the teeth. I have examined a great many now, and closely questioned my patients, and I find that even those who go to the best, or at any rate the popular, dentists have not been instructed either as to the importance of caring properly for the teeth or the dangers of not doing so. Artificial dentures cannot be kept clean without the use of some disinfectant. Some people are very particular in cleaning them, and succeed pretty well at the expenditure of a considerable amount of time, but I have never seen any from which some of the peculiar fur which collects upon them could not be scraped off, and from which an abundant and varied crop of organisms may be cultivated, as has been done for me by Drs. Sinclair Miller and Johnstone, pathologists of this town. This fur is most tenacious, and seems to be a microbial and yeast growth embedding in its meshes the salts of the saliva, very much akin, no doubt, to the tartar which collects on natural teeth.

Some people retain their artificial teeth in the mouth at night; this helps to preserve the contour of the face, and in the case of suction plates helps to retain them more firmly in position, and in some cases is absolutely necessary, particularly for public speakers.

Artificial teeth ought to be put into an antiseptic all night if they are taken out of the mouth. If they must be kept in, they ought to be put into an antiseptic solution for half an hour at night, and again for half an hour in the morning. The toothbrush, or plate-brush, should always be kept in an antiseptic; it will be an important thing to get toothbrushes which will stand this; the best bristle ones seem to stand it pretty well. This appears to be putting an additional burden on the patient, but, as ought to be explained to him, it is quite the reverse. There is then no longer any trouble in keeping the artificial dentures clean, no fur collects on them, and all they require is to be lightly brushed with a toothbrush or rinsed under the tap. I am quite certain that if the mouth can be kept more or less aseptic intestinal troubles and throat irritations will often be found to clear up in a wonderful way. In regard to the nature of the antiseptic to be used, I think I must leave it to the dentists to find out what will not act upon the artificial teeth or gums they provide; boracic acid I have found to be not strong enough to arrest the growth. It is rather important that the disinfectant should be cheap, as used twice daily it soon runs up a rather formidable bill.

Harrogate.

W. D'OLY GRANGE, M.D.

A GLANDULAR FEVER.

By the term "glandular fever" I do not mean that disease so designated in our textbooks, but one which a recent correspondent in the JOURNAL (April 16th, 1921, p. 582) has mentioned, of which I have had the opportunity of seeing five cases. It is an infectious disease of children characterized by a gradual onset, in fact so gradual that patient may walk into the consulting room complaining only of an enlarged neck and malaise. The temperature is rarely over 101°, and a mild inflammation of tonsils and palpable

cervical and inguinal glands are succeeded by a prolonged convalescence. That it is of infectious origin is borne out by the following evidence. There is slight inflammation of the tonsils, lymphatic extension, moderate leucocytosis, and moderate fever. I would say it was not contagious, inasmuch as my five cases were in widely separated families, and there was only one case in each family.

The first symptoms to appear are those of malaise and irritability, which last for a few days, to be followed by swollen cervical glands, which cause some difficulty in movement of the jaw. On the second or third day after this the inguinal glands become palpable and occasionally tender. On examination of the throat one finds a superficial redness of the tonsils, the tongue is coated, and in a severe case the gums and teeth are covered with sores, the corners of the mouth crack, and the lips have herpes with a resulting slight exfoliation. I have not observed nausea, but anorexia and constipation are the rule. The spleen and liver are not enlarged. The cervical glands are most markedly enlarged below the angle of the jaw; in fact, in three cases they were so swollen that I feared suppuration. The enlarged chain follows the anterior border of the sterno-cleido-mastoid muscle down to the sternum; the glands are distinct. In the inguinal glands they never reach the size of the cervical. The urine in three cases showed albuminuria; and in all cases there was a leucocytosis of 12,000 to 15,000; the temperature ranges from 101° to 102°. There is a slight increase in heart rate, and the chest is clear. In two cases there was slight enlargement of the legs. In one case there was otitis media. The child complained of earache in both ears, but only the left ruptured and discharged. I will relate the course of the one fatal case of the series.

I was called one Sunday morning to see a male child of 4 years who had been sick about a week. The cervical and inguinal glands were enlarged; the tonsils slightly enlarged, some swelling; a rather solid oedema of the legs; the heart and chest were normal; no temperature; slight leucocytosis, and a trace of albumin. The following Tuesday, when passing the home of the patient, I dropped in. On this visit I found the tonsils normal in colour, the swelling in the legs gone, the inguinal glands reduced in size, and the child feeling much better. I felt optimistic, and was much surprised to get a hurried call that afternoon. The child after a moderate meal at noon had gone to bed for a sleep, and on awaking was gasping for breath. When I arrived I found the child making desperate attempts to get its breath, all the voluntary muscles of respiration being brought into play. The extremities were becoming cyanosed; the heart's action was fast and feeble, and the child was at times delirious. This continued, in spite of stimulation and inhalations for nine hours, when the child died. At times the cyanosis would clear up, the child would become perfectly conscious, and the efforts at breathing less laborious, only to be succeeded by the former condition.

Discussion.—Among the possibilities in the fatal case might be considered involvement of the mediastinal glands from direct extension with consequent pressure. Secondly, thymic death, the infection calling for marked action on the part of the thymus, which responded by oversecretion, which had a depressing influence on the central respiratory centre, and hypertrophy with tracheal pressure. I regret that I was unable, because of violent efforts, to make a proper percussion of the sternum for dullness. As there was no suppression of urine and only a trace of albumin I doubt if the condition of the kidneys contributed to the fatal issue. As heart changes only appeared after the signs of asphyxia had continued for some time, I do not consider that pressure of the cervical glands on the vagus was an important factor.

Treatment.—Iodine ointment was rubbed into the glands twice a day, followed by a hot linseed poultice, a mild mouth-wash, and a gargle used every two hours. Internally much liquid was given as a diuretic, with small doses of calomel often repeated for the bowels, and a tonic of iron, quinine, and strychnine.

I very much regret my inability to obtain a *post-mortem* examination, and I did not obtain a differential blood count on the cases.

Sharbot Lake, Ontario.

S. F. LEAVINE, M.D.

A BLOOD STAIN FOR GENERAL PRACTICE.

HISTOLOGICAL examination of a stained blood film is of more service in general practice than is usually supposed, but it is not employed as often as it should be because it demands the use of delicate (and incidentally expensive) reagents, which require careful control because different samples differ so widely in their histological reactions. The practitioner, however, can often derive valuable assistance from a study of the histology of the blood (I do not mean a total count of cells), and it is frequently important that this should be made as quickly as possible. All that is required for rough clinical diagnosis is to determine the presence or absence of a leucocytosis, the presence of abnormal forms, and the proportion of the different cells present in the film. By this

means not only can intrinsic blood disease be detected but valuable assistance can often be obtained in the diagnosis and prognosis of acute disease. For instance, internal suppuration and typhoid fever can be recognized in the early stage, in the latter case long before the Widal reaction is positive. Many other instances can be given.

After much experimental work I have succeeded in devising a stain which does not necessitate the use of fine chemicals or of a delicate balance and volumetric apparatus. The method is as follows: Two test tubes are half filled with ordinary methylated spirit. To one about a small salt-spoonful of ordinary commercial methylene blue, and to the other the same quantity of orange G, is added. The precise amount does not matter so long as there is more than enough to produce a saturated solution. The tubes are boiled over a spirit lamp for about a minute and allowed to cool; the solutions are then filtered. By this means a saturated solution of each dye is obtained.

Roughly, one-third of the orange G is then added to two-thirds of methylene blue, the precise proportion again not being of vital importance so long as the methylene blue is in marked excess. The mixed stain is then filtered on to the blood film and allowed to remain for two minutes. Approximately an equal quantity of tap-water is then added with a fountain-pen filler to the stain on the slide and the solution is mixed by rocking the slide or stroking the top of the fluid with a penholder. This dilute stain is allowed to remain for two minutes. The slide is then drained and flooded with tap-water and left for a further two to five minutes. The film is then drained and blotted on filter paper (or fluffless blotting-paper) and allowed to dry in the air; heat should not be employed. The stained film should appear of a yellow-green colour. If an immersion lens is not available the specimen should be mounted in balsam with a cover-slip and examined with 1/6 in. objective. The scrutiny of the dried film without a cover-slip with an immersion lens is, however, easier. The red cells are stained yellow and the nuclei of the white cells blue, the nuclear structure being well defined. The granular and non-granular cells are quite distinct, it being easy, for instance, to distinguish between a mononuclear cell and a myelocyte. This method is not intended to supplant a further detailed examination by the haematologist. For the detection of primitive forms and an estimation of the resistance of the patient to the particular disease, and in prognosis generally, the services of a haematologist are usually required, but unstained films can be sent subsequently to a laboratory if required. I suggest, however, that the use of this stain and the rough information that can be derived therefrom may be of considerable assistance to the busy practitioner, and obviate the postponement of the diagnosis until a report has been obtained from a laboratory.

London, W.C. A. KNYVETT GORDON, M.B., B.Ch. Cantab.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SUSSEX BRANCH: BRIGHTON DIVISION.

The final clinical meeting of the session was held at the Royal Sussex County Hospital on June 15th. Tea was provided at the hospital, and a hearty vote of thanks was proposed by Dr. L. A. PARRY, honorary secretary, to the members of the honorary staff for the great assistance they had given in making the series of meetings so successful.

Mr. H. N. FLETCHER showed two cases of diverticulum of the bladder.

In the first, a man of 63, the pouch was a large one, of practically the same size as the bladder itself, as shown by bismuth injection and x rays. It was lying to the left side of the bladder, and the two communicated by a neck the size of one's thumb about midway between their adjacent surfaces. The symptoms were an intractable cystitis, with foul urine following a preliminary wash-out of the bladder, and a residual urine of about 16 ounces. The pouch was discovered accidentally during an operation for stone. After an attempt to shut off the pouch from within the bladder, draining the former meantime through a small incision in the outer border of the left meatus, which failed after a week, the pouch was excised extraperitoneally through an incision as for exposing the lower end of the left ureter. The operation was tedious, owing to the adhesion between the chronically inflamed pouch and the peritoneum and extraperitoneal fat above, and the pelvic fascia below and around it.

The second case was that of a man of 67, who had had a stone removed from the bladder two years previously. A recurrence of frequency and pyuria had taken place eighteen months later. A x-raygram showed two large stones, and per rectum a hard mass

was felt just above the left lobe of the prostate. One stone was found at operation to be lying free; the second was firmly embedded in a diverticulum, the narrow neck of which was situated just to the outer side of the left ureteric orifice. Through the neck, and grasped by it, protruded an excrescence from the stone. The neck was dilated with forceps, and eventually had to be nicked with a hernia knife before the stone could be extracted. The position of the pouch rendered its removal a very difficult matter and it was not attempted.

Mr. Fletcher also showed a specimen of volvulus of the small intestine in a newly born child.

When first seen, forty-eight hours after birth, the child had passed nothing per anum, was vomiting meconium, and was very distended. A finger passed readily into the rectum. A laparotomy was immediately performed. Distended coils of small intestine presented, and at a point about eight inches above the caecum the bowel was half twisted upon itself. This was undone, but the child died twelve hours later, still vomiting meconium. At the necropsy the small intestine below the twist was contracted, and the whole colon was small, firm, and solid-feeling, and nowhere larger than one's little finger. There was no atresia and some bile had passed down to a point just beyond the hepatic flexure. Below this the bowel contained firm, light grey, inspissated mucus only. It was evident, therefore, that the volvulus had occurred at some period of intrauterine life, and had only caused trouble when peristalsis started at birth.

Mr. J. H. TUNTON showed three cases:

1. A case of pseudo-coxalgia in a boy aged 14 years, with six weeks' history of pain in right hip with limp. No history of injury. General health unaffected. Slight limitation of abduction and of internal rotation, otherwise movement of right hip full, no tenderness or swelling. No visible wasting, three-eighths of an inch shortening. Radiograms showed marked flattening of the upper part of the femoral head with widening of the neck of the femur. This was considered to be a typical case of this condition, though the age was rather more than the usual.

2. A case of lumbosacral meningo-myelocoele in female infant aged 4 months, with paralysis of lower extremities and commencing hydrocephalus.

3. A portion of glass tubing, 3½ inches long, removed by suprapubic cystostomy, and stated to have been broken off a week previously during irrigation of his urethra by the patient. Anterior urethroscopy showed no injury to the urethra and cystoscopy a few small haemorrhages only. Foreign body heavily encrusted with phosphates.

Mr. A. BERESFORD showed a case of acute osteomyelitis of the right clavicle in a boy aged 13 years; total diaphysectomy was performed, and re-formation of a new clavicle took place in six weeks.

The patient was admitted to hospital on May 3rd, 1922. He was very ill with temperature of 104°, pulse 120, and swelling and redness over right clavicle. He had been taken suddenly ill two days before with pain in right clavicular region. Emergency operation: long incision over clavicle; bone found denuded of periosteum and lying in a bag of pus. The whole bone was removed and the wound packed open. Patient nursed in bed with sandbag between shoulders. At the end of four weeks there was definite formation of a new bone. A radiogram showed traces of new bone. On June 15th the wound was completely healed. A new clavicle had been formed, together with complete restoration of function of the right arm. No early massage or movements were employed.

Mr. FITZMAURICE-KELLY showed a case of gummatous arthritis of the elbow.

The patient, a man 49 years of age, came to the out-patient department complaining of swelling and stiffness of the left elbow, of six months' duration, which he attributed to an injury three years previously. The movements of the elbow were limited, the range of flexion and extension being from 160° to 80°; pronation and supination about 50 per cent. of normal. All these movements were painless. There was general thickening around the joint; a large cystic swelling over the back of the external condyle, and several hard nodular masses, about the size of a Barcelona nut, above the olecranon and under the triceps. Over the ulna, two inches below the olecranon, was a scar, the site of a swelling similar to that over the external condyle which discharged six months ago and took two months to heal. He also complained of pain in the right leg. There was marked irregular thickening of the crest and subcutaneous surface of the tibia. Skiagrams showed periostitis of the tibia and the upper end of the ulna. There was a history of a venereal sore twenty years ago.

[The report of the Wassermann reaction, received since the meeting, was "Positive 4."]

Mr. Fitzmaurice-Kelly also showed a case of osteochondritis of the upper end of the femur.

The patient, a boy of 14, was brought up with an indefinite history of limping for several years, but the condition had become much more marked in the last two months. The boy walked with a considerable limp, but briskly, and without pain. On examination there was marked wasting of the right thigh, which was two inches less in circumference than the left, and the limb was shortened three-quarters of an inch on measurement. Flexion was free and painless, but extension was very limited, and no abduction was possible. The permanent flexion was very limited, and no abduction was possible. The x-ray showed flattening of the upper surface of the head of the femur, some deepening and irregularity of the upper part of the acetabulum, and enlargement of the clear articular space.

Reports of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Section of Pathology was held in May, when Dr. T. T. O'FARRELL read a paper on a case of acute leukaemia with intraerania haemorrhage, illustrated with microphotographs and lantern slides, and the organs of the case. The President, Dr. O'KELLY, believed that many cases of haemorrhagic inflammation might turn out to be acute leukaemias if the blood during life and the organs *post mortem* were properly examined. Dr. O'SULLIVAN said that leukaemia was to be looked on as a tumour, and the larger proportion of nucleated cells in the capillaries of the liver and spleen compared with those in other blood vessels, as well as the definite collections of cells round the vessels of the brain, resembled to some extent the formation of secondary growths. Dr. CROFTON discussed the rise of temperature in the case. He had lately had a case of puerperal fever in which he had failed to obtain bacteria from the blood. If the fever in this case was not due to organisms but was of the nature of a tumour, the reason for the rise of temperature was obscure. Drs. SPEARES, WIGHAM, and BOXWELL also discussed the classification of leukaemias, acute and chronic lymphatic, acute early and chronic myelogenous, and others, with the different cells observed; and Dr. O'SULLIVAN stated that Mallory had reported that a number of cases of acute myelogenous leukaemia had been taken for lymphatic leukaemia. Dr. O'FARRELL, in reply, said attention had been directed during life to a search for bacterial infection, so that any possible changes in the cytology of the blood had been overlooked. The most probable diagnosis had appeared to be cerebro-spinal fever, but no cocci had ever been found. The case had apparently no terminal infection.

Dr. CROFTON read a paper on a new micro-organism, morphologically and culturally like the influenza bacillus, isolated from diphtheritic roup of fowl. With an antigen of this microbe he was able to prevent and cure the disease, and with a pure culture of the microbe to reproduce the natural disease and recover it from uninfected hens obtained from an uncontaminated source.

A meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland was held in May, with the President, Dr. A. R. PARSONS, in the chair, when Dr. L. ABRAHAMSON showed: (1) Electrocardiographs of a case of auricular fibrillation with normal rhythm still maintained five and a half months after treatment with quinine; and (2) a case of complete heart-block with multiple ventricular extra-systoles.

Colloid Therapy.

Dr. WALTER SMITH read a paper on the principles of colloid therapeutics. He said that colloids were to be regarded as an intermediate stage between coarse dispersions of matter on the one hand and true molecular solutions on the other. They simply represented a realm of matter differentiated, for practical purposes, from a continuous series of systems. The line of subdivision between colloid and molecular systems was arbitrarily drawn at a magnitude of particles of $1/1,000,000$ mm. in diameter. A large number of familiar examples of colloid dispersion among solids, liquids, and gases was afforded by such cases as foams, fogs and clouds, milk, smoke, liquid colloids, ruby glass, etc. The latent image on a photographic plate was a colloid phenomenon. Fine subdivision of matter involved an immense increase of surface area, and this was a point of capital significance in the interpretation of many chemical physiological phenomena. Several illustrations of the therapeutic action of colloids were given, and some experimental demonstrations illustrated—for example, the germicide action of colloidal silver, the influence of colloid manganese in controlling boils and other suppurative infections, and the use of colloidal copper. Any singularity in the operation of colloidal remedies might be ascribed to three chief factors: (1) Extremely minute subdivision (dispersion) of particles between the limits of $1/10,000$ and $1/1,000,000$ mm.; (2) consequent enormous increase in surface area (the reaction velocity of solids with liquids was proportional to the area of contact; adsorption played an important part); (3) activity of surface energy, the product of surface area and surface tension. Up to the present there was no good evidence that the chemical or pharmacological action of substances in the colloid state differed fundamentally from that in true solution, otherwise

than in the gradual slow effect due to the minute size of the particles and the enormous increase of surface area.

Dr. R. J. ROWLETTE read a note on the subject of rheumatoid arthritis and allied conditions, and mentioned various doctrines that had been held as to the causation of rheumatoid arthritis; he expressed his own view that the various forms of subacute and chronic arthritis were infective in origin. In his own experience the primary focus was most commonly in the mouth. He regarded many cases of myalgia, lumbago, and sciatica as of similar origin. He recounted his experiences of treating rheumatoid arthritis and allied conditions by autogenous vaccines, and regarded the result as supporting his view of causation.

MANCHESTER PATHOLOGICAL SOCIETY.

A LABORATORY meeting of the Manchester Pathological Society was held on June 14th, the President, Mr. J. Howson RAY, being in the chair.

Mr. GARNETT WRIGHT showed a series of specimens illustrating varieties of carcinoma of the rectum, and in addition a curious breast tumour for diagnosis. Mr. PLATT showed three interesting bone tumours raising points of diagnosis and treatment. The use of Colley's fluid was discussed by the President, Mr. MORLEY, and Mr. PLATT, the last-named speaker believing that the majority of alleged cures by means of this fluid to have been in cases of myeloma.

Dr. SELLARS presented a series of six specimens from the pathological laboratory of the Children's Hospital. One of these, after examination by members, was believed to be an intussusception of the appendix alone into the caecum. It was discovered by Mr. Warburton on exploring a palpable tumour in the right iliac fossa of a child of eight years. Resection was necessary. The specimen showed the appendix completely inverted within the caecum. Other specimens shown were bronchiectasis in a child, sarcoma of the small intestine and of the caecum, and the spleen from a splenic anaemia. Mr. DIGGLE showed a growth of the tonsil involving the larynx.

Mr. GEOFFREY JEFFERSON exhibited a histological section of a secondary carcinoma of the Gasserian ganglion. The primary growth was in the lung. The patient suffered from severe continuous facial neuralgia with hypoaesthesia, "anaesthesia dolorosa." The ganglion was explored, but nothing abnormal detected at operation. At autopsy six weeks later it was seen to be slightly swollen, and section proved it to be infiltrated with carcinomatous cells.

Mr. JOHN MORLEY showed two specimens of intrathoracic goitre and an acute perforative diverticulitis of the pelvic colon. He also showed a very instructive specimen—the oesophagus and diaphragm from a case of cardiospasm, the patient dying from perforated duodenal ulcer. The oesophagus was widely dilated, with thick muscular walls. Opposite the oesophageal opening in the diaphragm the gullet was strongly contracted. A histological section showed absence of fibrosis there. Mr. Morley thought that the crura of the diaphragm had not compressed the oesophagus, as the latter was not flattened but concentrically contracted. In discussion, Mr. JEFFERSON described a somewhat similar case, secondary to ulceration in the duodenum, but in this case the oesophagus was not hypertrophied. Mr. DIGGLE spoke of his own observations, and those of his colleagues at Ancoats Hospital, on the part played by the diaphragmatic crura in these cases.

THE eighty-first annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held from July 17th to 21st, inclusive, in the Royal College of Physicians and the University of Edinburgh. The first two days will be given up to meetings of the Parliamentary and Educational Committees and the Council. The annual meeting will begin at 10.30 a.m. on July 19th, at the College of Physicians; afterwards Dr. Nimian Bruce will read a paper on the treatment of early cases of mental disorder, and a luncheon will be given by the Chairman and Managers of the Royal Morningside Hospital. In the afternoon Professor George M. Robertson will deliver his presidential address on "The hospitalization of the Scottish asylum system," and the annual dinner will be held that evening in the Hall of the College of Physicians. On July 20th addresses will be given by Sir E. Sharpey Schafer, Sir F. W. Mott, Dr. David Orr, Professor J. C. Meakins, Dr. J. J. Graham Brown, and Dr. W. H. B. Stoddart. On July 21st a discussion on the treatment of mental diseases will be opened by Dr. Chalmers Watson.

Reviews.

POISONS.

THE scale on which the new *Traité de Médecine*,¹ edited by G. H. ROGER, F. VIDAL, and P. J. TESSIER, has been planned may be gathered from the fact that the sixth volume, wholly devoted to poisons, contains 506 pages, and that there are to be at least twenty-two volumes.

In a general introduction, occupying fifty-four pages, to the volume before us, Roger begins by making an attempt to give a definition of a poison. He opens with the proposition that any substance may be regarded as a poison which is capable of deranging the life of the anatomical units of the body by altering, directly or indirectly, the medium in which they live. Toxic substances, therefore, may come from without, or they may arise within the body. If this be accepted, poisoning would be defined as the sum of the disturbances induced, and would include the effects of lesions arising from a change in the chemical constitution of the internal medium. The human body is constantly on the verge of becoming poisoned. In evolving energy, and in the passage of bodily material from a complex and unstable condition to a simpler and more stable form, new substances arise within the cells and are thrown out into the lymph which bathes them; if not eliminated, they become possible causes of poisoning. The mineral salts in our food, the chemical and other products formed by intestinal ferments and by micro-organisms, may also give rise to intoxication. Roger describes at length several sources of auto-intoxication, and shows how some poisons, during their stay in the alimentary canal, are neutralized by the digestive juices: alkaloids, for example, may be precipitated and rendered harmless by any tannin which may be present; other materials, on the other hand, may become more toxic. Insoluble carbonates may be converted into soluble chlorides by the hydrochloric acid of the gastric juice, calomel may become sublimated, and potassium cyanide be converted into potassium chloride and hydrocyanic acid, and as the conversion of this last substance occurs mostly when the gastric juice is fairly free in the stomach this circumstance explains why potassium cyanide destroys life more quickly during digestion than when the stomach is empty. Roger reminds us that the conditions which regulate the absorption of general anaesthetics are of a physical order, as Paul Bert indicated, for the action of gases and vapours upon living tissue depends upon their partial tension. Blood circulating through the lungs absorbs any gas which reaches these organs until the tension of its vapours is equal to that of the gaseous mixture with which it finds itself in contact.

The various channels of absorption are discussed at length. Many attempts have been made to discover a relation between chemical constitution and the poisonous action of a substance, but no satisfactory result has yet been reached. In 1867 Rabuteau stated that metals are poisonous in proportion as their atomic weight increases and their specific heat becomes less, but this opinion is no longer held, for toxicity is now believed to be rather a question of the degree of the molecular dissociation of the salts of metals, estimated by their electrical conductivity. The complexity of organic bodies renders the determination of their toxicity difficult. It is known that the substitution of one radicle for another in such bodies considerably modifies the physiological action. As regards alcohols French chemists are of the opinion that their toxic properties increase with their atomic weight and point of ebullition. Before being absorbed into the blood poisons may undergo changes which may be favourable or unfavourable. A poison injected under the skin is less harmful than when passed into a vein. Strychnine can be injected into the foot of a guinea-pig after the particular vein of the leg has been tied, and when a few hours afterwards the ligature is removed no poisoning occurs, either because neutralization has taken place or because in consequence of the slow absorption of the poison elimination has kept pace with it. The harmful effects of a poison arise when it reaches the capillaries. Blood corpuscles have the power of transforming poisons; so too has the liquor sanguinis in consequence of its alkalinity. Poisons can be retained in the body for a long period; for example, lead in the intestine in the form of sulphide, in the skin as sulphate, and in the skeleton as lead phosphate. Objection may be raised to the

chemical forms in which lead is thus stated to be combined, for after all only minute quantities of the metal are present in the body at a particular time. Roger's remarks concerning the retention of poisons in the foetus are interesting and valuable both as regards lead and carbon monoxide, also as regards the passage of toxic bodies from mother to foetus and from foetus to mother. In some instances the foetus shows more resistance to certain poisons than the mother. This is said to be true of chloroform, chloral, and carbon dioxide, the explanation being the poorer development of the nerve centres in the foetus.

The subject of lead poisoning is dealt with by Marcel Pinard. Lead has seldom been used as a poison by criminals. It used to be thought that elderly people and the dark races were to some extent immune to lead poisoning, but this is no longer accepted. The reviewer has met with rather a serious form of plumbism in a negro. On one point practically all physicians are in accord—namely, that alcohol predisposes to the production of lead poisoning. Pinard describes the various channels by which lead enters the body; the alimentary canal is, he considers, the most frequent. He is of opinion that particles of lead become encircled in the digestive mucus by macrophages, and are then carried into the lymph channels or by the blood vessels to the organs wherein they become fixed. The symptomatology of plumbism is fully described. During colic Pinard states that the liver shrinks in size owing to contraction of the hepatic blood vessels. He states, also, that glycosuria may occur during colic, but this is not the experience of British physicians. The presence of basophil red corpuscles in the blood, paralysis of muscles, and morbid states of the kidney receive adequate attention.

Balthazard is responsible for the articles on arsenic, mercury, carbon monoxide, and illuminating gas. In its pure state arsenic is not poisonous, but it is readily oxidized, and when this has taken place toxic properties develop; 2 mg. of arsenious acid per kilo weight of body may when absorbed cause death in twenty-four hours. There is a personal idiosyncrasy to arsenic. When given by the stomach the symptoms will vary according to the vomiting which has taken place and any diarrhoea which may possibly have been induced. Graduated doses create a tolerance to the drug, as was shown years ago among the Styrian peasantry. Occasionally arsenical poisoning occurs in an epidemic form, as happened in the Midlands of this country some years ago, owing, as Reynolds of Manchester showed, to the consumption of beer in the manufacture of which contaminated glucose had been used.

The acute and chronic forms of mercurial poisoning are fully considered. Balthazard mentions the two theories advanced to explain the action of mercury. Some writers believe that mercury can only act by becoming converted, after absorption, into corrosive sublimate, and that this salt circulating in the blood forms a chloro-albuminate of mercury peroxide; others are of the opinion that the salts of mercury are primarily reduced to the vapour of the metal, for only in this form is mercury said to be capable of being absorbed.

The subjects of carbon monoxide poisoning, and of poisoning by opium, alcohol, cocaine, war gases, etc., are all attractively discussed.

The volume is a valuable contribution to our knowledge of the various subjects dealt with, and ought to find a place in the library of medical men and physiological chemists who are interested in problems of industrial medicine and in the various intoxications to which the human body is exposed.

PSYCHOPATHOLOGY.

THE volume on *Psycho-analysis, its Theories and Practical Application*,² by Dr. A. A. BRILL, one of the leading American exponents of Freud's teaching, has been considerably enlarged since it was first published in 1912. The most important additional matter is contained in a new chapter on paraphrenia. Under this heading Dr. Brill gives an account of a group of mild psychoses in which the subjects, though considered by their friends to be peculiar, eccentric, or crazy, seldom come under the observation of the physician. Such patients tend to be interested in "psychic" matters and thus sometimes come to the psychiatrist to discuss with him their views and experiences. The author finds that these individuals exhibit an attitude similar to that of the more

¹ Nouveau *Traité de Médecine*. Fascicule vi: Intoxications. Publié sous la direction de MM. les Professeurs G. H. Roger, F. Vidal et P. J. Tessier. Paris: Masson et Cie. 1922. (Sup. roy. 8vo, pp. 506; 23 figures, 4 coloured plates. Fr. 55.)

² *Psycho-analysis, its Theories and Practical Application*. By A. A. Brill, Ph.D., M.D. Third edition, thoroughly revised. Philadelphia and London: W. B. Saunders Co. 1922. (Med. 8vo, pp. 463, 21s. net.)

severe cases of dementia praecox, though naturally in a less pronounced form. There is a dulling of affectivity, a restricted capacity for work, some weakness of judgement, and eccentric notions, but with no actual dilapidation of the inner unity of the psychic life as in the graver cases. Such types are deserving of study, particularly because they afford an opportunity of elucidating the points of difference between a mild psychosis and a psycho-neurosis. The diagnosis is not always easy, but these mild paraphrenics, in contrast to psychoneurotics, cannot be influenced or moulded, are not impressionable, do not co-operate in treatment, and, as the author says, "a mental sclerosis runs through the whole life." Dr. Brill has had great experience in psycho-analytic therapy, and it is thus of interest to observe that he finds the paraphrenic type inaccessible to mental exploration. The impenetrability of these cases is a feature of diagnostic importance, and most psychiatrists have found them to be almost entirely uninfluenced by any of the usual forms of psychotherapy.

Dr. Brill, like all good Freudians, attaches much significance to the little mistakes in life. Amongst these, as he points out, are to be included misprints and the failure to notice errors in correcting proofs. There are several misprints in this volume, and a rather unfortunate misuse of the word "predisposed" for "presupposed" occurs on the first page of the preface. It would be interesting to know how the author explains this slip. He writes a little crossly of his opponents in the sentence preceding that in which the mistake occurs, and perhaps this may have something to do with it.

The same author has also written another volume, *Fundamental Conceptions of Psycho-analysis*,³ which is intended for the information of non-medical readers. The material in this book is taken from lectures given at an elementary course in the Department of Pedagogics at the New York University. The book is clearly written, and the author's wide experience of his subject enables him to illustrate the theories he advocates by references to a number of concrete examples which serve to support them.

SANITARY INSPECTION.

The systematic inspection of his district is one of the most important duties of a sanitary officer in this country, and many of the recommendations made to sanitary authorities result from that inspection. In the United States of America the inspection is given the more high-sounding title of Public Health Surveying, and its great importance is coming to be recognized by the American public health authorities. In *Public Health Surveys*⁴ Dr. MERRAY P. HORWOOD, of the Massachusetts Institute of Technology, defines such a survey as "an investigation conducted by a trained corps of workers, in order to determine the exact status of those conditions that may affect the health of a community directly or indirectly." A cursory glance at this volume would stamp it merely as another public health textbook, but it is something much more than that: it indicates in a very practical manner under appropriate headings what defects should be looked for, where they may be expected, and precisely how they may be remedied. Watersupplies, drainage and sewage disposal, refuse

specifically dealt with. The chapter on milk supplies is of special interest to public health administrators in this country, for we are constantly hearing of the excellence of the American methods. We cordially agree with the author that a safe milk supply in a community is almost as important as a safe water supply; indeed, we would go farther and say that, at the present day, it is quite as important. He lays great stress on the advantages of pasteurization and goes so far as to say that one of the greatest boons conferred upon mankind was the introduction of this process, an opinion that is not held by a large number of health officers outside America. He is, however, wise enough not to rely entirely on pasteurization, for he is eloquent in advocating well-constructed, clean, well-lighted, and well-ventilated milking sheds, and urges the importance of absolute cleanliness in

connexion with every stage of milk production. The system of score cards in vogue in America, though it has never found much favour in this country, is well described, and the various cards in use are reproduced. Illustrations are given of model cowsheds very much on the lines of those recommended by the Board of Agriculture and Fisheries in the Board's leaflet (No. 241) on the construction of cow-houses. Other illustrations depicting insanitary conditions, such as accumulations of manure right up to the walls and doors of cowsheds, testify to the fact that the milk supply of America is not produced throughout that continent as satisfactorily as some persons would have us believe.

Although this work is primarily intended for American public health officers, it contains a great deal of information of value to those of other countries. School medical officers especially should read the chapters on school sanitation and school hygiene. The problem of the drinking cup in schools is very difficult of solution, and one method is illustrated for use in those schools where running water is not available. A large jar with a tap at the bottom is provided, and a few inches below the tap a wide funnel is placed with the outlet emptying into a bucket. When the tap is turned on the water flows into the funnel, out of which the child drinks, as he does out of the more costly fixed "bubbling fountains" which are found in some schools. A foreword from the pen of the late Professor William T. Sedgwick and an introduction by Mr. George C. Whipple, Professor of Sanitary Engineering at the Harvard Engineering School, give an additional interest to this work, the value of which is further increased by the large number of illustrations; there is one on every fourth page.

SIR THOMAS ANDERSON STUART.

In his biography of *Anderson Stuart, M.D., Physiologist, Teacher, Builder, Organizer, Citizen*,⁵ Mr. WILLIAM EPPS, Secretary of the Royal Prince Alfred Hospital, Sydney, with which the late Sir Thomas Peter Anderson Stuart was intimately associated from the year after its opening until his death, gives an authoritative account, based on close personal knowledge of a many-sided and striking character. Anderson Stuart was born in Dumfries in 1856, and after an exceptionally brilliant career at Edinburgh, culminating as demonstrator of physiology under Rutherford, was appointed in 1882 professor of anatomy and physiology in the infant medical school of the University of Sydney, which owes its present highly developed state of efficiency to his labours; this was his life's work, and to accomplish it he to a large extent sacrificed original laboratory research, though he did a certain amount of work in connexion with the functions of the epiglottis, the internal structure of the eye, chromogen⁶ operation⁷ (called "Stuart's terrible rito"), and kymoscopes. On his arrival at Sydney in 1883 there was no school or students; in 1914 there were 604 students of medicine. His administrative and organizing ability, in conjunction with his pertinacity of purpose and his shrewd knowledge of men, was invaluable in the building up of the medical school and all that concerned it. His activities extended in wider directions, for he was President of the Board of Health of New South Wales, of the Royal Society of New South Wales, and of the University of Sydney Society for Combating Venereal Disease. This memoir, which contains much autobiographical material, and gives a graphic and sympathetic sketch of a forcible man and his personal traits, is illustrated by photographs and by four caricatures, thus throwing light on the respect felt for their teacher by the younger members of the university for which he did so much.

NOTES ON BOOKS.

In a small monograph on the operation of submucous resection of the nasal septum⁸ Dr. MEDDAUGH DUNNING gives a brief account of the anatomy and physiology of the nose and traces the development of the technique which he now employs for this operation. He advocates especially the use of a curette-elevator of his own design. The book is freely illustrated, but there is little in the text which is original and much which is irrelevant.

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

HOW TO READ THE SCOTTISH TRIAL RESULTS.

WHILE the Royal Scottish Automobile Club, like the Royal Automobile Club, is unable to create what might be called new fashions in cars, nevertheless by recent enterprise both organizations are helping to pave the way to the production of vehicles that will suit the needs of owner-drivers in particular better than those hitherto available. Thus even in the case of the Manx motor racing for the Tourist Trophy and for the "Fifteen Hundred" Trophy, which is really one of the final phases of experimental work, very valuable progress has been made under three headings, among many others—namely, in the direction of the evolution and use of mixed fuels with power alcohol as an essential ingredient; in the evolution of brakes to all four wheels; and in the demonstration of the fact that the corded type of tyre makes for amazing durability and economy and will presently be available, without undue weight, on the straight-sided principle with light rim. The mixed-fuel proposals will interest medical men in very practical fashion at no distant date, for some of our largest fuel-distributing organizations have already completed plans for engaging in the business on a commercial scale. These mixed fuels are evolved in measure as the liquid-fuel internal-combustion engine is developed.

THE COMING OF MIXED FUELS.

If the standard car trial in Scotland, or the special racing cars run in the Isle of Man, or, more particularly, those which will be raced for the Grand Prix on the Strasbourg circuit in the middle of this month, be examined, it will be found that the greatest progress is being made in the direction of producing more power from smaller engines. This is made possible by the use of compression ratios far higher than those formerly employed. For example, when the war broke out a $5\frac{1}{2}$ to 1 compression ratio was considered almost too high even for aircraft engines; whereas the Vauxhall cars raced in the Isle of Man had compression ratios of about 7 to 1, and several cars that will figure on the Strasbourg circuit will have at least that. One result is that we are getting 90 h.p. out of a 2,000 c.c.m. engine, or what we should call approximately a 14-h.p. type "Treasure" rating. But these powers, which are capable of propelling chassis at extraordinarily high speeds, are being developed with an amazing fuel economy, particularly if we cast our minds back to the days when we were racing with engines of ten times the volume that figured in the "Fifteen Hundred T. T.," the earlier vehicles achieving only 60 per cent. of speed on an easy course and under better weather conditions than obtained in the Isle of Man last month, when the miniature engine vehicles were raced. In other words, a glance at the story of racing reveals plainly that we have been reducing car weight, increasing reliability, and reducing the engine space in relation to the chassis space, as well as the fuel and tyre consumption in relation to the work done. Special bi-fuel carburetors are ready for standardization; and the motorist will have the opportunity of choosing either to develop greater horse-power or to save 25 per cent. of his fuel bill and develop as much power as at present, or to combine parts of the two gains.

But at present, though the straight-sided tyres certainly make for economy under the most severe test of all—namely, racing, wherein the wheels have to be skidded round the corners and the side strains are therefore at the maximum, nevertheless the weight of the detachable rims is at present an objection to their immediate universal use. Information of which I am possessed, however, leaves me no manner of doubt that this particular weight problem will be solved at no distant date. Further, the risk of the detachable rim rusting *in situ* is likely to be eliminated by the materials that will be employed. Already it is possible with the corded tyre on the beaded-rim principle to obtain an average of two and a half times the tyre mileage that was possible with canvas tread tyres. When it shall become possible to use a straight-sided tyre without extra weight and without any possibility of the rim rusting, tyre mileage will be increased still more. Thus already we have reached the point at which tyre costs are lower than they were before the war if we put them on the only possible scientific basis—namely, cost per car mile.

POINTS ABOUT SMALL CARS.

In the recent trial of standardized small cars by the Royal Scottish Automobile Club, the awards in connexion with which were published in these columns last week, it is interesting to note that, though under the heading of tyre trouble each competitor was allowed six minutes during the whole week in the course of 1,020 miles running without being penalized, only one competitor of the forty-four who started exceeded that allowance; and that by a margin of three minutes only. From this the conclusion might be drawn that these cars are adequately tyred as a class. But I think it would be an erroneous one. At least, the impression I gathered myself when watching some of the hill-climbing work in the Highlands was that there is a tendency by the trade to under-tyre small cars as a class. Curiously, in the other extreme there is a tendency in some of the middle-class cars to over-tyre. One useful result of the Scottish trials will, I think, be to cause some of the leading makers of small cars to fit larger tyres next year. But as long as we use the beaded-edge type of tyre, which is likely to be with us for another season or two in the majority of cases, there is no question that it is necessary to have proportionately somewhat larger tyres, both for comfort in riding and as to the air space, to ensure the necessary strength. Vast improvements have been made in the corded tyre, and I gained another impression in Scotland concerning tyres for small cars. I am quite sure some of the competitors strove to save their springs in what was certainly a punishing test—many of the road surfaces were of an extremely irregular character—at the expense of their pneumatics by running them somewhat slackner than the tyre makers specify. This is a foolish policy and is bound to lead to trouble. No car owner should ever slacken his tyres with a view to saving his springs; it is sure to result in nipping, ripping, or otherwise destroying the tubes, while the wrong sort of play occurs to the walls, particularly when corners are taken; therefore the treads get worn out untimely.

THIS YEAR—AND NEXT.

In face of the very great proportion of hill climbing that had to be done in the course of the tour and of the fact that some of the ascents over which the competitors were not timed were of more severe gradient than those over which they were it means a deal for these little cars to average 20 miles an hour from point to point. Indeed, I have in mind one particular hill climb, not in the timed area, along the descent following which we were riding in a big 6-cylinder car at from 10 to 12 miles an hour only because the back axle was crashing against the side members of the car frame every now and again the moment we went any faster, so irregular was the surface of the mountain road. The driver of this non-competing, lightly laden car tried to soothe our anxiety when we hinted that we might be getting home, somewhat late by saying that it was impossible that the small cars could go as fast as we over that route. I pointed out, however, that according to their showing they would keep up the schedule, though, admittedly, on some of the steeper ascents they could not average 20 miles an hour on the climb; therefore their only chance of keeping to schedule was to go over the ground we were traversing at 10 to 12 miles an hour at 25 or 35 miles an hour. That is precisely what they did, it being quite remarkable how closely these little vehicles kept to schedule. I saw them come in at the end of that day's run, as on other nights. Quite 80 per cent. of the competitors came in within a minute of their schedule time on a day's run of anything from 160 to 180 miles. The tests showed clearly that these little vehicles can be built to stand rattling over bad roads. Further, the club's method of examining the cars that appeared to do best in the Trials at the end of the test, to make sure that they really were in good condition before granting awards, is a wise move, and makes such awards of additional value.

Some would urge that the trials should be extended next year to embrace vehicles with engines up to 2,000 c.c.m. volume, instead of setting the limit at 1,600 c.c.m. as this year, but that would be a mistake. There is no particular need to try vehicles as large as 2,000 c.c.m. engine volume in tests of this sort next year. There will be forthcoming then quite as many 1,600 c.c.m. vehicles as even the Royal Scottish Automobile Club itself could handle because many members of the British, and European, industry who abstained this year have suddenly recognized the value of what is the most scientifically conducted and all-round test of standard small cars ever attempted; moreover, the relatively few awards given

increased their value. Next year also the American industry will have fully entered on the light car business, and as the Scottish classification of standard vehicles is on a price basis the Americans, with their low costs, would have every advantage in competing, and will assuredly do so in considerable numbers. We should therefore rather reduce the engine volume from 1,600 to 1,500 c.cm. than put it up from 1,600 to 2,000 c.cm. for the 1923 Scottish standard small car trial, in which German products are sure to be represented.

ASPECTS OF FUEL CONSUMPTION.

The report on the trial published by the Royal Scottish Automobile Club occupies 39 foolscap pages, and is the most valuable document any intending purchaser of a small car can study. The figures under all heads are of extreme interest, including brake tests, acceleration, six different hill climbs, and fuel consumption tests. The last-named are particularly interesting when fresh forms of fuel and carburettors suitable for their use are about to be developed. The leading carburettor firms are fully prepared for the coming change, which will give us still further economy to an extent aggregating some 25 per cent. on present performances. Yet some of the present-day performances in the small car class, as now certified by the Scottish trial figures, are extremely economical.

It does not follow, however, that cars which are the most efficient as standardized in relation to one another, or to their classes, will necessarily make the greatest appeal under this head to the average user. It depends entirely on what the vehicle does. For example, if we take the order of merit in all classes for the entire competition, we find that the first place went, as was mentioned last week, to a 11.4-h.p. 4-seater Citroën car. It happened to be one of the heaviest cars in the trial, weighing 2,502 lb., and did 41.112 ton miles to the gallon; but because of its weight the actual road miles that car did to the gallon of fuel was 36.802. To the non-technical, therefore, there were plenty of cars that ran cheaper than this. For example, one 10-h.p. 2-seater G.N., which came out 19 in the order of merit of fuel consumption, and weighed 1,394 lb. when competing, did 30.342 ton miles to the gallon only, but travelled 48.723 road miles to the gallon. The motor owner has to pay the petrol bill for his vehicle in terms of road miles to the gallon; consequently one wants to consider the statistics under their two headings. Again, sometimes there are unexpected variations. Thus, a second 11.4-h.p. Citroën car, which weighed somewhat more than the machine that came out best under fuel consumption, scaling 2,527 lb., did 37.485 ton miles to the gallon and 33.243 road miles to the gallon as a 4-seater.

TON MILES v. ROAD MILES.

I find that a 2-seater 10-h.p. G.N. which competed in the lowest class for cars costing not more than £250, did 35.123 ton miles to the gallon, which, however, in the case of this car, which scales 1,442 lb., worked out at 54.59 road miles to the gallon. The two 9-h.p. air-cooled Stoneleigh cars, which also competed in this class, and which did best on the hills alike on time and on formula and in many other respects came out first and second in their class, were notable for carrying three passengers throughout the trial, and weighed 1,691 lb. and 1,617 lb. respectively, did 35.993 and 38.582 road miles to the gallon respectively. Among the 2-cylinder water-cooled two-seater cars one 7-h.p. Wolseley weighed 1,647 lb., did 22.527 ton miles to the gallon, and did 30.623 road miles to the gallon; while a sister machine weighed 1,579 lb., did 21.71 ton miles to the gallon and 30.796 road miles to the gallon. The 10-h.p. 4-cylinder water-cooled Swift weighed 1,786 lb., did 35.178 ton miles to the gallon and 44.113 road miles to the gallon; but it did not distinguish itself on the timed hill climbs. One of the two-seater 8-h.p. 4-cylinder overhead valve engined Talhots weighed 1,778 lb., did 31.267 ton miles to the gallon and 39.425 road miles to the gallon, doing notably well on hills, as did the sister machine, which weighed 1,745 lb., did 31.524 ton miles to the gallon and 40.501 road miles to the gallon. By contrast one 10-h.p. 2-cylinder air-cooled B.S.A., which, like the sister machine, carried two persons throughout the trial, weighed 1,795 lb., did 30.565 ton miles to the gallon and 38.135 road miles to the gallon, but did not distinguish itself particularly on the timed hills. Nor did the sister machine, which weighed 1,817 lb., did 28.206 ton miles to the gallon and 34.767 road miles to the gallon. The 11.9-h.p. Star cars did notably well on the hills, and in other respects, one, weighing 2,391 lb., doing 37.120 ton miles to the gallon and 34.727 road miles to the gallon; while the sister machine weighed 2,425 lb., did 34.492 ton miles to the gallon and 31.879 road miles to the gallon. The 11.9-h.p. A.C. weighed 1,953 lb., did 24.156 ton miles to the gallon and 27.712 road miles to the gallon, being thirtieth out of forty-four competitors in order of merit in fuel consumption in the whole trial, and last but one of its class in order of merit on hill climbs and speed tests on formula. One of the 12 h.p. Talbot-Darracqs, both of which carried four men throughout the trial,

weighed 2,934 lb., did 35.932 ton miles to the gallon and 27.432 road miles to the gallon; and the sister machine weighed 3,018 lb., did 33.205 ton miles to the gallon and 24.655 road miles to the gallon.

BRAKES, ACCELERATION, AND HILL CLIMBING.

The order of merit in regard to the brake test showed that the following came out best in their respective classes:

9-h.p. Stoneleigh, 7-h.p. Wolseley, 10-h.p. Swift, 11.9-h.p. Star, and 12-h.p. Talbot-Darracq. The order of merit in each class in the acceleration test showed the following cars did best: 9-h.p. Stoneleigh, 8-h.p. Amilcar, 8-h.p. Talbot, 11.9-h.p. Star, 12 h.p. Talbot-Darracq. The hill-climbing and speed tests marks on formula showed the following cars to be the best of their respective classes: 9-h.p. Stoneleigh, 8-10-h.p. Rob Roy, 8-h.p. Talbot, 11.9-h.p. Star, and 11-h.p. Riley.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

The third annual meeting of the Society for the Prevention of Venereal Disease was held at the house of the Royal Society of Medicine on June 29th.

LORD WILLOUGHBY DE BROKE, who presided, said that the general situation was the same as when he addressed a similar meeting a year ago. The Ministry of Health had not found itself able to apply the teachings of science to the prevention of venereal disease. There were, however, some hopeful indications that the National Council for Combating Venereal Diseases might presently co-operate with the Society. He quoted from the eight-point manifesto of the Council, published in 1921:

"If an individual has incurred or has reason to think that he or she has incurred risk of infection, it is his or her bounden duty to cleanse himself or herself thoroughly and immediately."

This appeared to be a complete acceptance of the policy of immediate self-disinfection. Moreover, in the *Venereal Clinic*, edited by Dr. E. R. T. Clarkson, formerly a member of the National Council, it was stated that the National Council "have fundamentally moved from their original position to one which is practically shared by the Society for the Prevention of Venereal Disease." Even more telling evidence than this was available. A work by Sir Leslie Mackenzie, which had received the endorsement of the National Council, contained the following:

"It is absurd to say that there is any danger in teaching every person capable of being taught that the venereal diseases are each of them due to a definitely known germ; that, so long as the germ lies on the surface, it can be destroyed with a mild disinfectant or even mechanically removed by soap and water without much trouble; but that when one of those germs enters the channels of the body and infects the lymphatic glands or the blood, the destruction of the germ, which is another name for the cure of the disease, becomes, in at least two of these diseases, a matter of extraordinary difficulty and demands high technical knowledge and skill."

Lately (Lord Willoughby continued) there had been some decrease in the incidence of venereal disease in this country; the decrease synchronized with the public controversy on immediate self-disinfection, and the consequent publication of a great deal of knowledge which had hitherto been concealed from the public. In France, according to the report of the French commission of inquiry, one-tenth of the population were suffering from syphilis, the deaths due directly or indirectly to this cause numbered 140,000 a year, and the cost of syphilis alone was several milliards of francs. He rejoiced in the setting up of Lord Trevellyn's Committee, and in this connexion he referred to a letter by Lord Dawson which had appeared in the press, and which urged that—

"Until some conclusion supported by a considerable preponderance of opinion has been reached it cannot be reasonably expected that the Ministry of Health should do otherwise than maintain impartiality and give a fair field and no favour to the two schools of thought and action. As a logical consequence grants of money should be made either to both or neither of the corresponding societies."

Lord Willoughby thereupon proposed a resolution that the Ministry of Health should again be approached with a request for financial support to assist the society in carrying out its policy.

This resolution was opposed by Mr. HAROLD COX, who thought it would be more polite to await the decision of the Committee of Inquiry, and he was supported by Sir BRYAN DONKIN and others. Eventually it was agreed unanimously that as soon as the Committee of Inquiry had reached a decision the Ministry of Health should be approached on the subject.

Mr. WANSEY BAYLY, honorary secretary, gave an account

of the various activities of the society during the year, chiefly meetings and correspondence, and mentioned that Penbrooke-shire had been added to the local authorities, now numbering twenty-one, which had adopted the society's policy. Sir W. ARBUTHNOT LANE, the treasurer, said that subscriptions had fallen below last year's level, but the work had been done at loss cost.

Dr. MEARNS FRASER said that Portsmouth, of which he was medical officer of health, was the first large town to adopt officially the policy of instructing the public in methods of self-disinfection, which it did by means of leaflets and notices in public places. The result was reflected in the numbers attending the treatment centre. The centre was opened in February, 1917, and in that year 352 individuals applied for treatment. In 1918 the numbers applying were increased by 91 per cent. above this figure, and in 1919 by 62 per cent. above the figure for 1918. In 1920, in the latter part of which year the policy of instruction in self-disinfection was adopted, the increase upon the previous year's figure was only 13 per cent., and in 1921 there was no increase at all, but a decrease of 12 per cent. upon the figure for 1920. In the first five months of 1922 there had been a decrease of 23 per cent. as compared with the corresponding months of 1921. The figures were too small and the period too short to permit of absolute deductions, but he thought they had some significance.

The annual report was adopted unanimously, and various committees were reappointed.

REVISION OF THE INTERNATIONAL SANITARY CONVENTION OF 1912.

The International Sanitary Convention signed at Paris on January 17th, 1912, marked an important stage in the gradual progress that is being made towards the adoption by all civilized countries of a national and uniform system of preventing the maritime spread of dangerous epidemic diseases. The official delegates of forty countries signed this Convention, but difficulties and delays arose in its formal ratification by the Governments concerned, and down to September, 1919, only twenty Governments had performed this act, some of them with, and some without, certain reservations.

In the meantime it had become evident that early revision of the Convention would be necessary in view of new political conditions and new developments of science. Plague, cholera, and yellow fever were the only diseases dealt with in it, and the additions to epidemiological knowledge since 1911, when it was prepared, were such that even as regards those diseases some of the technical provisions were out of date and did not conform with modern views and practice. The Office International d'Hygiène Publique was at that time, and still remains, the body primarily concerned with the preparation and formulation of international health agreements, and its committee, at its session in October, 1919, unanimously accepted the necessity and importance of an early revision. At the next session, in April, 1920, it was arranged that the delegates of the countries represented should prepare detailed proposals for amendments or alterations, and that these would form the basis of the preliminary studies necessary in order that a formal international conference might afterwards be convened to decide on the provisions of a revised Convention. Expert examination of the modifications proposed was begun at the October session of the same year and was continued at each subsequent session. The task of revision was greatly facilitated by working on the lines of a memorandum which was the outcome of combined action taken during 1920 by the delegates of all the British countries concerned. The aim was to produce an international document which should on the one hand provide a more efficient means of preventing the spread of epidemic diseases, and on the other hand keep fully in view the interests of commerce and traffic, by removing arbitrary "quarantine" rules and customs which are not justified by present knowledge. Most of the proposals in this memorandum were accepted and acted upon in the revision undertaken by the Committee, and the position at the end of last year was that the preparation of a revised draft of Articles 1 to 54 of the Convention, comprising Part I (general provisions), was completed. It is understood that the principal changes proposed include:

1. A better system of prompt international notification of the occurrence and progress of the epidemic diseases dealt with.

2. The addition of provisions relating to typhus fever, small-pox, and certain other diseases.

3. A rearrangement by which the action to be taken is stated separately for each disease in accordance with up-to-date knowledge of its natural history and epidemiology.

With regard to Parts II to IV (special provisions for Eastern and Far Eastern countries, pilgrimages, the Sanitary Board of Egypt, etc.), various circumstances made it impracticable to consider their revision until the technicians who had charge of the preparation of the new draft could acquire local knowledge of present conditions in the countries concerned. The Office International d'Hygiène Publique, owing to the limited funds at its disposal, was not in a position to appoint a Commission for this purpose, and the project only became feasible when the Health Committee of the League of Nations decided at a session held in Paris in October, 1921, to send a small Commission to collect information as to the risks of spread of epidemics from the Black Sea ports through the Straits, and from countries in the Near and Middle East through the Suez Canal. In consultation with the President of the International Office it was arranged that the reference to this Commission should include a study of matters bearing on the revision of Parts II to IV of the Convention and that its personnel should include members of the permanent committee of the Office who were specially occupied with that subject. The President (Dr. Th. Madsen) and Vice-President (Sir George Buchanan) of the Health Committee of the League of Nations were among the members appointed, and as technical adviser Dr. Granville, President of the Sanitary Maritime and Quarantine Board of Egypt, accompanied the Commission throughout its inquiry, which began at Alexandria on February 20th and ended at Constantinople on March 27th.

The League of Nations has just issued this Commission's report,* which describes from the point of view of international interests the measures necessary to prevent the spread of epidemic disease in regard to:

1. The Suez Canal and ports, whose sanitary service falls under the Sanitary and Quarantine Board of Egypt.
2. The Red Sea (the Mecca pilgrimage and the Hedjaz railway).
3. The Mediterranean littoral of Asia Minor.
4. Constantinople and the Straits.

The report shows clearly the difficulties and delays arising from the post-war multiplication of different authorities whose present practice, not being governed by international or local agreement, causes vexatious and costly interference with commerce, but, in the absence of proper sanitary stations and equipment, is of little or no value in preventing the introduction and spread of disease. It relates that at nine successive ports of call during a voyage of nine days from Beyrout to Constantinople the ship was medically inspected under different regulations, and without reference, other than an examination of the bill of health, to the previous inspections. It describes new circumstances in Arabia which show clearly the need for comprehensive and co-ordinated measures of sanitary control if the annual pilgrimage to the sacred cities of the Hedjaz is not to continue to cause, from time to time, widespread prevalence of cholera and other epidemic diseases. It emphasizes the necessity of effective measures at the northern entrance to the Bosphorus, and notes that the present sanitary station at that entrance (Kavak) is inadequate, dilapidated, and otherwise objectionable from its restricted area and bad landing facilities. Suggestions are given for remedying in detail these and other local defects, with regard, in each instance, to the requirements of the International Sanitary Convention of 1912. An annex contains the text of a draft revision of Parts II and III of that Convention.

This concludes the preliminary study which was required before all the civilized countries of the world could be approached with a view to holding a formal international conference for the revision of the 1912 Convention, and it is greatly to be hoped that the established procedure for this object will now be carried through without delay.

* League of Nations C.342 M.193, 1922, III, "Report of Commission to enquire into international arrangements regarding epidemic disease prevention in certain areas of the Near East (basin of the Eastern Mediterranean and Black Sea) and in connection with the Mecca pilgrimage."

British Medical Journal.

SATURDAY, JULY 8TH, 1922.

THE PROPOSED INCIPIENT INSANITY BILL.

IN our Parliamentary Notes last week (p. 24) it was stated that the Minister of Health had under consideration the draft of a bill to enable persons suffering from incipient mental disease to be treated in public or private mental asylums without certification. This proposal follows upon the inclusion of a clause dealing with this subject in Dr. Addison's ill-fated Ministry of Health (Miscellaneous Provisions) Bill, which was introduced into Parliament in the autumn of 1920. With the withdrawal of this bill all the proposals in it had to be abandoned, but the importance of the treatment of incipient insanity is a subject which has grown rather than diminished in the interval. At the Annual Meeting of the British Medical Association at Newcastle-upon-Tyne in July, 1921, an interesting discussion took place upon the subject in the Section of Neurology and Psychiatry. It was introduced by Professor G. M. Robertson of Edinburgh, who contrasted the English with the Scottish law; in the former, if an insane person be detained and restrained he must be certified, but in Scotland a "lunatic" may be detained and treated under certain conditions without being certified. He pointed out that private patients were entering such mental hospitals as Craig House in greater numbers voluntarily than under certificate, and that they came at an earlier and more recoverable stage. He suggested that if the lunacy laws could be so amended that patients of small means suffering from curable mental disorders could also enter mental hospitals and receive early treatment without being certified lunatics, as patients enter general hospitals, and as the majority of private patients in Scotland paying the higher rates of board now did, then a new era would be introduced. He did not suggest that the Scottish law upon the subject was ideal; the Act relating to admission of patients to mental hospitals in Scotland was sixty-five years old, and in Scotland, as in England, the Lunacy Acts had outgrown their usefulness, especially to the poorer classes of the community.

The discussion at last year's Annual Meeting was but the latest chapter in the long history of the close interest that the British Medical Association has taken in the treatment of incipient insanity. As occasion has offered the Association has either urged the need of legislation or has made representations to the Government of the day in respect of bills which have been introduced, and as the result the Association has had the satisfaction of seeing many of its proposals embodied in the law of the country. For example, several amendments were introduced into the Lunacy Amendment Act of 1890 as the direct outcome of representations made by the Association in response to the request of the Government. A committee of the Association in the years 1897-98, with the valuable co-operation of the Medico-Psychological Association, collated evidence as to the Scottish experience, and laid it before the Lord Chancellor (Lord Halsbury) with a joint recommendation from the two Associations that the English law should be modified in the same way.

The introduction into the Parliament of 1905 of a Lunacy Acts Amendment Bill indicated acceptance by public authorities of the principles for which the medical

profession had long been striving. This bill incorporated, with other detailed improvement of the lunacy law, the methods of the Scottish Act for the treatment of cases of unconfirmed mental disease. Although, owing to the exigencies of public business, this and also Sir John Batty Tuke's bill for the early treatment of mental disease were not passed, their introduction showed that the time was opportune for the definite formulation of the views of the medical profession on the subject, and a small subcommittee was therefore appointed by the Medico-Political Committee of the Association in 1905 to consider amendment of the law concerning the treatment and detention of persons suffering from incipient insanity. In 1906 the Annual Representative Meeting in London considered and approved two special reports of the Medico-Political Committee dealing with amendments of the Lunacy Acts, and more particularly with the provision for unconfirmed cases of mental disease. In 1907 the Annual Representative Meeting at Exeter considered and approved a statement of evidence which was submitted on behalf of the Association to the Royal Commission on the Care and Control of the Feeble-minded. The report of the Royal Commission was issued in 1908, and in August, 1909, the Association was represented on a deputation to the Home Secretary to urge the necessity of early legislation to give effect to this report.

In 1911, following a communication concerning the care and control of the feeble-minded from the Manchester and Salford Sanitary Association, requesting the support of the British Medical Association in making representations to the Government as to certain methods of dealing with this matter, the Council of the Association gave instructions for a special report on the subject to be drawn up and submitted to the Representative Body. This report summarized the work the British Medical Association had already done during the previous ten years in regard to the care of the feeble-minded, and reviewed the representations which it had also made to the Government, with a statement of the reforms in the law which the Association advocated as a result of its experience.

The Medico-Political Committee continued to give close attention to the subject, and in 1912 the Association submitted a memorandum to the Home Secretary on its policy with regard to the amendment of the lunacy laws on the care of the feeble-minded, pointing out particularly its views on the new classes of patients which ought to be brought under the supervision of the Lunacy Commissioners, the composition of the Lunacy Commission, the need for one central authority, and the need for the treatment of unconfirmed mental disease. In the reply which the Home Secretary sent to the Association he stated that he had under consideration the details of a bill to provide for the care and control of the feeble-minded. Subsequently this bill was introduced into Parliament, in the session of 1912-13, and in general met with the approval of the Association. Though, owing to the demands on Government time, the bill was withdrawn, it was reintroduced in March, 1913, and subsequently became law under the title of the Mental Deficiency Act. The scope of this Act was limited, and in 1914 the Association appointed certain members to represent it in a discussion with representatives of the Medico-Legal Society upon the question of the treatment of incipient insanity without certification. A Voluntary Mental Treatment Bill was introduced into the House of Lords in July, 1914, and the Council of the Association expressed approval of this bill, which was intended to secure that persons whose mental condition was uncertain, but who required medical treatment to prevent their becoming lunatics, might receive such treatment in a manner at present impracticable owing to

the state of the law, which assumed that a person either was or was not insane, and took no notice of early symptoms of insanity. This bill, being an unofficial bill, had no binding effect upon anyone, and the only positive achievement of its introduction was that through it public information was given as to the legislation that was proposed in regard to the treatment of incipient insanity.

Another bill was introduced into the House of Commons in 1915 by Mr. Cecil Harmsworth, then Parliamentary Under-Secretary to the Home Office; its purpose was to facilitate the early treatment of mental disorder of recent origin resulting from wounds, shock, disease, stress, exhaustion, or any other cause. The object of the bill was to secure the proper treatment of such cases by making the law less rigid, and it was especially intended to apply to cases of soldiers and ex-soldiers whose unstable mental condition had arisen from war causes. In consequence, however, of opposition it was found impossible to proceed with the bill.

Although the details of the legislation now proposed have not yet been made public, it may be assumed that in general they will follow the provisions of the various bills dealing with incipient insanity that have come before Parliament during the past fifteen or twenty years, but have not been proceeded with. It is probable, therefore, that they will refer to patients in private as well as public mental hospitals approved by the Board of Control, and not only to patients who are willing to enter an institution, but also to those suffering from puerperal mental disorder and similar conditions where the patient has no clear power of volition. The procedure suggested is, we understand, that a declaration shall be made by two doctors, one of them approved by the Board of Control, to the effect that the patient is suffering from mental disorder, and is likely to benefit from temporary treatment in an institution, so that it is expedient for him to be received into an institution for this purpose. Such a declaration would hold good for a limited period—probably six months—at the end of which time another declaration might, under suitable safeguards, be made. The patient throughout would have the right to leave the institution, subject to giving forty-eight hours' notice. The measure, it is hoped, may help the public to look upon all mental institutions as hospitals offering increasing possibilities for the cure or arrest of mental disorders, and not as asylums in which persons are segregated for life. It has been difficult to convince the Legislature that the powers of the Board of Control may be usefully extended from "certified" to "uncertified" persons, in spite of the evidence from Scottish experience. Medical opinion is, however, unanimous that the present laws on the subject of insanity are in urgent need of reform in order that persons, particularly in the early stages of insanity, may reap the benefit of modern advances in the science of psychiatry, and this, it is to be hoped, may be gained from the new bill.

THE CASE OF THE SENIOR SURGEON COMMANDER.

Not for the first time, we have to call attention to the hard case of certain medical officers of the Royal Navy. For more than two years this grievance has been before the Council and the Naval and Military Committee of the British Medical Association, and many efforts have been made to induce the Admiralty to redress it, but without avail. It now becomes our duty to set out the story and point the moral. The facts are briefly as follows:

In January, 1920, as a consequence of the report of the Jerram-Halsey Committee, new regulations for

retirement came into force in the Royal Navy. It was at once seen that a great injustice had been done to a considerable number of surgeon commanders who were nearing or who had passed the new retiring age of 50. The grievance arose under two heads—age of retirement and rate of pension. Under the new regulations these medical officers were compelled to leave the service from one to five years earlier than would have happened under the original terms of their appointment. The effect of this was to penalize the senior surgeon commander in two ways. In the first place he was deprived of several years of service at a higher rate of pay, and in the second place his chances of promotion to higher rank—and therefore of increased pay and pension—were correspondingly diminished. A special hardship was inflicted on those officers who, when making provision for old age, had taken out endowment policies to mature at the normal age of retirement; they found themselves saddled with heavy insurance premiums, which had to be met out of a halved income. Again, the Jerram-Halsey Committee had recommended increases of retired pay for all branches. Now, up to that time it had been recognized, in fixing rates of pay and pension, that the medical officer, with his long professional education at his own expense, was entitled to substantially better remuneration than the executive and other officers who obtained their special training wholly in the Service. But whereas under the new regulations the officers of other branches got increases of pension varying from 26 to 100 per cent., the surgeon commanders received only 10 per cent. increase.

Thus these medical officers, who had entered the Service on the understanding that they would be allowed to serve until the age of 55, were compulsorily retired at 50, and their maximum pension was fixed at £600 a year, representing an increase of but 10 per cent. on the former retired pay of their rank. Here it must be noted that 20 per cent. of the new pension for all officers was stated to be in respect of the increased cost of living, and the pension was accordingly liable to a reduction of 20 per cent. should the cost of living fall to the pre-war level. It followed that if this provision were carried out to the full the surgeon commander might in the long run find himself with a pension lower than he would have drawn had the increase never been granted. It has taken more than two years to obtain an assurance from the Admiralty that in no case shall the retired pay of a surgeon commander who was on the list on July 1st, 1919, be reduced below the old maximum of £547 10s.

The whole grievance of the senior surgeon commander was fully set out in a communication made by the British Medical Association to the Admiralty at the end of 1919, when a request was made that a deputation might place the views of the Association before their Lordships. The Admiralty's reply contained much argumentative matter but no hope of redress, and the deputation was refused. The grievance was admitted, but with the cold remark that legislation for cases of individual hardship was not practicable. Now the Association's case from the first has been that the better pay of those remaining in the Service is no justification for ill-treating the officers who are removed before their time; and that this is not a matter affecting two or three individuals alone. The new regulations have been unjust to some eighty or more surgeon commanders who were or who are approaching the new age of retirement.

The Admiralty's answer was considered so unsatisfactory that in March, 1920, a further letter was sent, asking once more that a deputation should be received, but the Admiralty, in its reply, repeated its preference for written communications. A year later the Association wrote again, insisting that a distinct injustice seemed

to have been inflicted, and giving details in support of its case. This letter was sent direct to the First Lord of the Admiralty. In his reply Lord Loo said that he fully appreciated the very small extent to which the pension of these particular officers had been raised, and that he realized that even this small increase was reduced by the loss of pay which some of them had no doubt suffered as the result of compulsory earlier retirement; but the Board, he said, had to regard the new scheme as a whole, and could not modify it to meet the needs of a particular group without giving rise to similar claims from others. Efforts were next made to enlist the sympathies of members of Parliament, but as nothing came of this a further letter was sent to the Admiralty on February 24th, 1922, expressing the considered view that the treatment of these medical officers amounted to a breach of contract which, in the case of a private firm, would have led to the institution of legal proceedings. The Admiralty was now warned that if the question could not be settled satisfactorily the Association would feel obliged to place the facts before the profession, and to advise young medical men that if they entered the Royal Naval Medical Service they must do so in futuro with the knowledge that any agreement made with them by the Admiralty might be broken. The answer to this was that the Admiralty could not depart from its original decision. In the meanwhile a scheme for reductions in other branches of the Service had been issued, and this included provision for compensating officers who agreed to retire voluntarily before a certain date. This gave occasion for one more effort towards a just settlement, and the Council of the Association wrote asking that the senior surgeon commanders should be dealt with on similar lines, but again the Admiralty declined. Thereupon the Council at its last meeting resolved to make a final protest and to repeat in more emphatic terms the warning already given.

The matter is one of elementary justice. The complacent bureaucrats have refused to give way, heedless of the effect of their attitude upon the future of the Service for which they are responsible. It is the considered opinion of the British Medical Association that the Admiralty has inflicted a serious injustice upon senior surgeon commanders. The Lords of the Admiralty, it seems, are unmoved by words addressed to them. The Association must therefore now address itself to those from amongst whom the recruits for the Naval Medical Service are drawn. In the light of what has now happened its advice to medical students and young practitioners is to consider seriously the disadvantages to which they are liable if they place their careers in the hands of the Admiralty. This warning will be repeated in the annual Educational Number of the BRITISH MEDICAL JOURNAL, and elsewhere as occasion arises.

R.A.M.C. WAR MEMORIAL: UNVEILING CEREMONY AT THE ABBEY.

WE announced more than a year ago that the fund to establish a memorial to the officers and men of the Royal Army Medical Corps who lost their lives in the war amounted to nearly £19,500. Of this sum £1,500 was earmarked by the donors for the benefit of the families and dependants of the fallen. It was decided that the amount available for the purposes of the memorial itself should be used in three ways: to erect in Westminster Abbey a tablet commemorating the officers and men of the R.A.M.C., Regular, Territorial, and Temporary, who fell or died in the war; to inscribe their names in a "Golden Book" placed in the Chapter House of the Abbey; and to contribute the sum of £10,000 to the fund for the restoration of the Abbey. This project commended

itself to all concerned, and its execution was entrusted to a committee consisting of the Director-General Army Medical Service (Chairman), Sir Norman Moore, Bt., Major-General Sir W. G. Macpherson, Sir Laucelotto Gubbins, and Staff-Sergeant Walton, with Colonel C. R. Tyrrell and Major E. B. Waggott as joint secretaries. The main part of the work has now been completed, and on Thursday next, July 13th, at noon, the Duke of Connaught, Colonel-in-Chief of the Corps, will unveil the memorial tablet in the nave of the Abbey. His Royal Highness will then present to the Dean and Chapter for the purposes of the Abbey Restoration Fund the sum of £10,000 in fulfilment of the third part of the scheme. Music will be provided by the Abbey choir and the band of the Welsh Guards. The memorial tablet is of marble, the work of Mr. Wilcoxson of the Royal School of Art, South Kensington; the inscription makes reference to the "Golden Book." The tablet is on the north side of the nave, near the west door and on a level with the foot of the Unknown Warrior's grave. The preparation of the "Golden Book" is in the hands of Mr. Grafton Hewitt. Service uniform, academic robes, or morning dress will be worn at the unveiling ceremony. Subscribers to the fund desiring seats should apply to the Royal Army Medical Corps Memorial Fund, Room 314, War Office, London, S.W.1.

THE FUND FOR RUSSIAN DOCTORS.

WE reproduced last week (p. 26) the appeal on behalf of starving medical men and their families in Russia addressed to all members in Great Britain and Ireland by the four officers of the British Medical Association. The Council on June 14th had unanimously resolved that this appeal should be made and that every member be asked to send a subscription of 5s. It was felt that the quickest and most certain way of obtaining subscriptions would be by direct appeal from the head office to each member and that the limitation to a small sum would go far to secure a prompt and widespread response. A leading article commending this appeal to the British medical profession was printed at page 19. The Association received a list of doctors and families of deceased doctors in Russia to whom food parcels must be sent without delay if they are to be saved from death by starvation, and this list has been taken to the American Relief Administration in London, together with the first instalment of the money already received. The American Administration makes itself responsible for the delivery of a food parcel to each of the sixty-five persons named in the list, and will get a receipt from them. It promises further that all moneys subscribed through the British Medical Association will be used for the relief of doctors or the families of doctors who are in urgent need of food. Nine subscriptions of 5s. each will more than cover the cost of one parcel, including all charges. Contributions should be addressed to the Financial Secretary of the Association, 429, Strand, W.C.2, who will send a receipt. It will not be possible to acknowledge all the names of subscribers in our columns, but the amount of money collected will be announced from time to time. The total sum received up to July 3rd in response to this appeal was £685. Many members have sent sums in excess of the 5s. suggested by the Council, and in view of the plight of the Russian medical profession and the urgent need of relief for those of its members who are threatened with starvation the Financial Secretary has not hesitated to accept these generous gifts. A large number of other members have inquired whether more money will be needed, and the Financial Secretary, while unable to reply personally to each, asks us to say that further sums would be gratefully received. One medical man in sending his cheque encloses a letter for publication, giving first-hand information of the sufferings of our Russian colleagues; we print this at page 67, and have respected the writer's preference for anonymity. We may add here that the American Relief Administration has informed the Medical Secretary that next to the necessity of the Russian doctors for food is their need

for medical supplies; it hopes shortly to undertake the sending of medical supplies for some 100,000,000 people and 175,000 hospital beds.

VENOMOUS FISHES.

DR. H. MUIR EVANS of Lowestoft, who has contributed several papers on the subject to our columns, brought the results of his investigations of the defensive spines of fishes, living and fossil, before the Royal Society at its meeting on June 15th. The existence of a poison gland in connexion with the serrated spine on the tail of the sting ray has been a matter of dispute since the days of Aristotle. It has usually been held that the toxic effects of a wound by this spine were due to the poisonous property of the mucus, and that there was no special poison gland. Sections of the spine showing the cellular structures of the two lateral grooves which lie on either side of the median ridge facing the whip-like tail are difficult to obtain. But complete sections show that the grooves are occupied in their deepest portion by alveolar connective tissue provided with blood vessels and lymph channels, and separated from the more superficial mass of special epithelial tissue by a pigmented capillary meshwork. This epithelial tissue contains columns of cells in an active state, the secretion of which is discharged towards the lateral dentate margin. A study of the dorsal fin spine of the spiny dog-fish, *Acanthias*, reveals a groove containing a glandular structure which discharges secretion through a median longitudinal pit. Further investigation discloses the presence of a more complex gland on the posterior aspect of the dorsal fin spines of the Port Jackson shark, *Cestracion*. There is some evidence, also, of a special glandular structure near the base of the lateral teeth of *Chimaera monstrosa*. The examination of the fossil fin spines of *Cestraciontidae* reveals the existence of a rough surface with either median or lateral teeth, which may have been occupied by glandular structures similar to those found in *Cestracion*. The surface of the spine is otherwise covered with enamel which shows bosses or ridges running in a longitudinal direction. The fossil fin spines of the *Pleuracanthidae* were also described and discussed in view of the probability of the presence of glandular tissue in the fresh state; and the similarity between the head spine of *Pleuracanthus* and the caudal spine of the sting ray was pointed out. The poisonous effect of the Malay sting rays and the uses that the venom is put to by the natives were described. Clinical observations on wounds by the spines of dog-fish have been confirmed by inoculation experiments. Fish inoculated in the lateral line showed a great increase in the respiratory rate, and passed into a somnolent condition. They showed a tendency to lie flat on the side of the puncture, and there was often a spastic condition of the muscles at the site of inoculation; if the fish recovered from the immediate effects of the venom, it developed an area of pink oedema of the muscles which did not go on to suppuration, and was not accompanied by intra-peritoneal or other haemorrhages. The venom of the weever is more deadly; it produces intense and agonizing pain, and there is haemorrhage in experimental inoculation both at the site of the puncture and in the peritoneum. Injection of the venom is followed in fish by paralysis of the muscles on the side of inoculation, and in small laboratory animals by paralysis of the hind quarters. If the dose is insufficient to kill the animal by its effect on the respiration, an abscess forms at the site of puncture, and *post mortem* there is found a pure necrosis of the muscular tissue. Weever venom is a powerful haemolytic poison, and is also leucotoxic and so breaks down the resistance and allows a rapid bacterial infection to take place. Dr. Muir Evans found that filtration of glycerin extracts of the venomous spines of the weever through filter paper or a Berkefeld filter removed a constituent of the venom and deprived it of its haemolytic power on washed red corpuscles. Haemolysis did not take place with filtered venom unless a small quantity of serum heated to 60° C. was added, or a solution of lecithin; with unfiltered venom, however, haemolysis took place without

the addition of any activating substance. Experiments were described showing that the efficacy of the native remedy, *Abrus*, used against the effects of wounds produced by *Synancea*, a member of the *Scorpaenidae* found in Réunion and Mauritius, depended on a physiological antagonism between *abrin* and the haemolytic constituent of the venom. Practical methods of treating the wounds produced by venomous fish were described.

SNAKES AND THEIR VENOMS.

THE poisonous snakes of Africa were the subject of an "occasional lecture" at the Royal Society of Medicine on June 28th by Lieut.-Colonel H. Watkins-Pitchford, R.A.V.C. The lecture was not of the narrow, zoological character that the title might suggest, but contained a good deal of interesting fact and philosophy about snakes in general. Although there has been an age-long antagonism between the seed of the woman and the seed of the serpent, which finds frequent expression in classic sculpture (for instance, in the *Laocöon* in the Vatican), a truce has been called occasionally—witness the association of the snake with *Aesculapius*, perhaps also the raising of the brazen serpent by Moses in the wilderness, and the guarding of the sleeping Buddha by a cobra. The revulsion with which snakes are commonly regarded tends, the lecturer stated, to disappear among those who have to do with the reptiles in captivity; familiarity breeds tolerance, and even liking. The anatomy, especially of the mouth parts, of the two great classes of snakes—the viperine and the colubrine—was described. The viperine snake was capable of inflicting a much deeper wound than the colubrine. In the puff adder, one of the viperine snakes, he had seen five perfectly canalized fangs of decreasing size. As the viperine snake struck, the fang was brought into the erect position, but the ejection of venom was not a purely mechanical process, and some snakes at least had the power of preventing the expression of venom even when the fang was fully erected. The snake seemed to realize that the number of rounds in its pouch was limited, and it did not use its poison apparatus unless it was frightened or provoked. It killed its small prey generally by a stroke, and only when its victim was refractory or elusive did it emit the venom. With the exception of the Australian tiger snake, the snake with the most toxic venom was an African variety, the black mamba, whose venom had twice the toxicity of that of the puff adder. The amount required to kill a man, judging from the amount required to kill a rabbit, was one-fifth of a grain. He had dissected out from the poison fangs of the black mamba about 2½ grains of venom, so that this creature possessed sufficient armament at any one time to kill twelve or thirteen persons. The toxicity of snake venom, however, varied according to the time of year. There was a widespread belief that snakes were more poisonous in the spring, and it might be that seasonal changes influenced not only the activity of the gland but the contents of the secretion. The second most deadly African snake was the *Naja nigricollis*, or black-necked spitting snake, so called from its power to eject venom for some distance. Under excitement the neck structures of this snake became enormously swollen, but this was more than intimidation, like the bristling of the lion's mane. The power of ejecting venom in a jet or spray was possessed chiefly, if not entirely, by the hooded snakes. Contact of this venom with the eye set up intense conjunctivitis and permanent loss of sight sometimes ensued. In the collection of venoms chloroform was not necessary if the operator was active and competent. The reptile was seized directly behind the head with a ratchet forceps, lifted from its cage, the mouth opened by depressing the lower jaw with the underside of a watch-glass, and the poison sac squeezed with the forefinger, the poison being caught by the glass as it dripped from the fang. The snake was then soled with a raw egg and put back in its cage. This process could be repeated several times with the same

reptile. Venoms acted in various ways: colubrine venom acted primarily on the respiratory centre, and viperine primarily on the vasomotor centre. Evidently, to judge from the post-mortem indications given by Shakespeare, it was from colubrine venom that Cleopatra died:

Here, on her breast,
There is a vent of blood and something blown:
The like is on her arm.

Not often was death so dramatic as Shakespeare pictured it:

Tremblingly she stood
And on the sudden dropp'd.

The fatal result with colubrine poisoning did not usually take place until after the passage of some hours. With viperine venom, should the fatal result be postponed or averted, the delayed effects were much more serious and pronounced than with colubrine venom, and there was widespread tissue involvement around the bite. Unfortunately, owing to the time limit, Colonel Watkins-Pitchford had to curtail his lecture, and to omit altogether what he had proposed to say about the preparation of antitoxins. Sir Leonard Rogers, in proposing a vote of thanks, said that he had investigated the action of the venom of the African puff adder some years ago and found the essential effect of the bite to be a vasomotor paralysis.

SPIRIT PHOTOGRAPHS.

THERE is a society or club known as the Magic Circle which consists of professional conjurers, but admits a few approved amateurs, to the kindness of one of whom, a distinguished member of the medical profession, we are indebted for a copy of a report, dated May 31st, issued by the Occult Committee of the Circle. This committee, which consists of expert conjurers, has been appointed to investigate what are called "spiritualistic phenomena," and at the suggestion of Sir Arthur Conan Doyle appears to have turned its attention first to spirit photographs. The report deals with the inquiries made by the committee into the claims of two people—a man and a woman—who it was alleged were producing spirit photographs of a remarkable nature in unopened packets of photographic plates. Neither of the mediums came out of the ordeal unscathed. When a fraud-proof packet was sent to the male operator he obtained no results. He stated that the packet had twice been "held," but that the "usual sensation" had not been felt. As soon, however, as a packet that could be tampered with was submitted, a "psychic extra," as it appears to be called, was obtained on one of the plates. Unfortunately for the performer the conjurers had tampered with the packet first. In addition to other tests, a straight line of red varnish (invisible in the red light of the dark room) had been painted across the top left side of the edge of the stack of six plates. On the return of the packet by the medium three of the red marks were found at the bottom, showing that these plates had been reversed. When the operator was asked for an assurance that the packet had really been returned unopened, he replied in the affirmative. He said that it was quite usual to get adverse remarks from persons who did not understand, and that such remarks were not worthy of notice. Shall we admire the power of spirits, or deplore the frailty of human nature? The lady medium was vouched for by Mr. and Mrs. Hewat McKenzie, who conduct an institution known as the British College of Psychic Science. Three sittings were held with this medium. First, two members of the committee secured a private sitting. It was required that the plates, enclosed in a sealed packet, should be sent for "magnetization" some days in advance, and at the sitting these plates were exposed, and on development "extras" were on most of them. On one a face was visible in the midst of a cotton-wool effect; the others had crude markings, ascribed by the medium to unformed "ectoplasm" or to "spirit lights." As will be observed, she had acquired some of the latest spiritualistic terminology. At the second sitting, arranged by Mrs. McKenzie, a sealed box of six plates, forwarded in accordance with instructions, was produced by the medium. The box was opened and the plates transferred to metal dark slides; a service was then

held, hymns being sung, and the Lord's Prayer recited. The plates were then exposed and an "extra" appeared on one of them—on No. 1 plate—which the investigators satisfied themselves had been substituted for the first plate of the original package. The medium had by this time become suspicious and nervous, and in fact she was not equal to holding her own with professional conjurers. She, however, consented to a third sitting, and for this an unopened box of unprepared plates was sent. It therefore became necessary that the plates should be secretly marked before being placed in the dark slides. One of the investigators, having placed the open stack of plates before the medium under the ruby light, secretly attached a small pad of pink material, chemically prepared, to the ball of his right thumb, and in handing the plates one by one to the medium an invisible mark was impressed on each. The medium gathered up the slides, and going into the studio took them to a small table on which her handbag was standing. The ostensible object was to obtain the hymn-books for the service, but the move being anticipated, the members of the deputation placed themselves in convenient positions to observe her actions. The hand holding the slides was seen to be placed inside the bag; one slide was dropped into a side pocket and a duplicate slide picked up with the hymn-books. Four plates were developed, and on one which did not show the mark a "spirit extra" appeared. All this may be amusing to the cynic, but the conclusions the committee of the Magic Circle draw are that although spirit photographers, like conjurers, meet changing conditions by the adoption of new methods, there are at present at least two methods in general use by some, at least, of the mediums who devote themselves to obtaining photographic "extras." In the one case, when the plates are accessible before the sitting, the spirit form is impressed, in advance, by contact with a selected transparency. In the other, when the packet is not available beforehand, the exchange for a prepared plate is made by a subtle move after the original plates have been loaded into the dark slides. The committee assert that they have never imposed a test which would not have served to demonstrate the straightforwardness and honesty of the medium, and conclude with a promise to extend to any honest medium fair, impartial, and courteous treatment, and to give him a free hand to carry out the experiment in his own way.

A MEDICAL PLAYWRIGHT.

THE doctor as dramatist is a figure of considerable importance in the modern theatre, as witness Telokhov in Russia, Arthur Schnitzler in Austria, Henri de Rothschild in France, and Somerset Maugham in England. The name of Frank G. Layton (whose new play, in six scenes, *The Prophet*,¹ has lately been published) is likewise favourably known, in the rather smaller if more eclectic world of the English repertory theatres, as the author of *The Parish Pump*, *The Ferriport Election*, and other character comedies of the present day. *The Prophet* is cast in a different mould; its action takes place at Jerusalem in the Old Testament times of the campaign of Sennacherib against King Hezekiah. A parallel may be drawn between this play and one written by Arnold Bennett a year or two ago. *Judith* was brisk and engaging enough to read, but it failed upon the stage, in spite of a highly spectacular and picturesque production and some excellent acting. Such might also be the fate of *The Prophet*, and for like reasons. We have enjoyed reading this play, but for acting purposes its interest seems a little too diffuse: the attention wanders from character to character, the scenes fall away instead of being cumulative, and the climax—when it comes—is disappointing. Again, the colloquial dialogue, while entertaining, is not always "in the picture." Dr. Layton can, of course, point to the successful employment of modern terms and dialogue in Shaw's *Caesar and Cleopatra* and in other plays, but not mixed thus: "Poet: 'This Prophet is hot stuff. . . . Officer of Guard: May the Lord God strengthen

¹ *The Prophet*. A play by F. G. Layton. London: C. W. Daniel, Ltd. 1922. (Cr. 8vo; pp. 91. 3s. 6d. net.)

his tongue." The same kind of criticism might be made of the farcical episode in Scene V, where the citizens of ancient Jerusalem take up unaccustomed arms and are drilled on the stage in military evolutions. Where, however, Dr. Layton is particularly interesting to us is in the application of his medical knowledge to dramatic purposes—curiously enough, not often done by other medical playwrights—for in his play the attack of Sennacherib's army against Jerusalem is beaten off by no feats of Jewish valour but by the outbreak of an epidemic of plague carried by rats. As a piece of literary work *The Prophet* has many merits and it will interest and amuse medical readers, although we may confess to preferring Dr. Layton in his other and more familiar dramatic vein. We have ventured to criticize this work because we regard him seriously as a playwright.

WATER-BORNE ENTERIC.

EPIDEMICS of enteric fever are not now so common in this country as they were, but when they do occur they are generally traced to specific pollution of a public water supply. An instance which occurred in 1921 at Bolton-upon-Dearne, in the West Riding of Yorkshire, was investigated by Dr. W. Vernon Shaw on behalf of the Ministry of Health, and his report has just been issued.¹ It appears that after almost entire freedom from the disease during the previous five years, enteric fever somewhat suddenly became prevalent in the urban district during the second half of July and the early part of August; a few cases were reported also in the adjacent urban district of Darfield and a few more in nearby villages in two rural districts bordering on Bolton-upon-Dearne. The epidemic began with cases of diarrhoea and gastro-intestinal disturbance, followed a fortnight or three weeks later by definite cases of enteric fever. This is not uncommon in water-borne outbreaks of enteric in which recent faecal contamination of the public water supply has occurred. The first crop of cases was followed by others due to secondary infection, and altogether the first outbreak comprised 137 attacks and 16 deaths. A second outbreak began early in October and cases were notified down to December, the total amounting to 260 cases and 29 deaths. The second outbreak was almost entirely limited to Bolton-upon-Dearne itself, which has a population of about 3,581, and is included in the urban district of that name, the total population of which is 11,947. Thus from July to December, 1921, some 351 persons were stricken down by enteric fever in the urban district, of whom 40 died. Including 46 other cases, which occurred in districts immediately adjoining Bolton-upon-Dearne, of which 5 were fatal, the grand total of the two outbreaks was 397 attacks with 45 deaths, giving a case mortality of 11.3 per cent. Dr. Shaw, after reviewing the various causes likely to have given rise to the outbreak, excluded everything but the public water supply. In 1875 the Dearne Valley Waterworks Company began to supply the district, and the original source, a deep well, was gradually augmented by other sources. In April, 1921, the Waterworks Company was superseded by the Dearne Valley Water Board, which supplies four urban districts and certain parishes in two rural districts. Different parts of the area receive their water supply from separate sources, and in 1921 the prevalence of enteric fever did not affect two of the urban districts supplied by the Water Board. The water for Bolton-upon-Dearne is pumped from some abandoned workings of the Dearne Valley Colliery. The colliery is still being worked, but there appears to be no danger of pollution of the water in the abandoned workings, which is locally known as the "clean" side of the colliery; the water is collected in an artificial pound built of brick and concrete, which is quite impervious to seepage from the workings. The colliery, however, lies under an inhabited area, only part of which has been sewered. In the inhabited area is a wood which, during the coal strike (April to July, 1921), was raided by the strikers for fuel. In the wood and its immediate

neighbourhood the sandstone rock overlies the coal measures, is near the surface, and shows many cracks and fissures. A considerable amount of human excreta was observed among the undergrowth and in ditches. During the hot and dry weather of June, 1921, the ground overlying the colliery was baked and cracked, and it is suggested that after rain impurities were carried down the cracks and fissures in the rock and reached the water in the colliery. Bacteriological examination of samples of this water in August shewed it to be contaminated. Bolton-upon-Dearne itself, to which, as has been said, the second outbreak was almost entirely limited, is regarded as the most insanitary portion of the urban district. The water in the public mains was chlorinated during the whole of September, and the bacteriological report on samples taken was favourable. It appears that the people in Bolton had for some weeks given up using the public supply, and had resorted to a public pump which drew water from a shallow well immediately beneath it in the sandstone rock. This well had undoubtedly become specifically contaminated. For many weeks the weather had been hot and dry, but on October 2nd and 3rd there was heavy rainfall; it is believed, however, that surface pollutions had been drawn into this well during September. Early in November the water was found on bacteriological examination to be contaminated. People also used wells, and the water from these also was polluted. Close to the pump well just mentioned is a disused quarry in which the rock shows extensive fissures some 12 inches wide. The lower part of the quarry, which is used as a playground, is 10 feet above the level of the well; the floors of privy middens in this part are all several feet above the bottom of the well. The village feast took place on August 20th, and itinerant showmen and others camped with their caravans and roundabouts in a field above and adjoining the quarry. A good deal of human excrement and refuse accumulated in one corner of this field. A heavy strain was imposed upon the Bolton-upon-Dearne urban district council in dealing with the epidemic, especially in finding accommodation for the 260 patients of the second outbreak. Fortunately the isolation hospitals of a number of local authorities became available. In addition, an infant school was made into a temporary hospital for 30 cases, and later was extended to accommodate 43 patients.

INTERNATIONAL ASSOCIATION OF MEDICAL MUSEUMS.

THE fifteenth annual meeting of the American and Canadian sections of the International Association of Medical Museums was held at the Army Medical Museum, Washington, D.C., on May 1st. There was a large attendance, including representatives of the medical services of the American and Canadian Governments. The chairman, Dr. James Ewing of Cornell University, emphasized the growing importance of the association because of its devotion to the interests of the science of morphology, which must ever remain the fundamental branch of medicine. The programme of scientific business dealt principally with museum technique and morphological pathology. Bulletin VIII ("Journal of Technical Methods") and Bulletin IX (the "Sir William Osler Memorial Bulletin") were ordered to be published. It was agreed that the Exchange Bureau and Bureau for the Preservation of the Results of Medical Research of this section of the International Association should be transferred from the McGill University Medical Museum to the United States Army Medical Museum in Washington. An interesting feature of the afternoon session was the presentation of a testimonial from the Medical Department, United States Army, to Dr. Daniel Smith Lamb, assistant and pathologist at the Army Medical Museum from 1865 to 1920. The presentation was made by Brigadier-General Walter D. McCaw, Assistant Surgeon-General, who outlined the work of Dr. Lamb and called attention to the results of his labours, as illustrated by the collections of the institution in which the meeting was being held. Dr. F. B. Mallory of Boston was appointed president, and the other officers were elected for

¹ Reports on Public Health and Medical Subjects, No. 12. H.M. Stationery Office, 1922. (Pp. 41. 2s. net.)

the ensuing year. At the close of the scientific programme the meeting adjourned to inspect the large recent accessions to the Army Medical Museum and a series of special exhibits from members of the American Association of Pathologists and Bacteriologists and its conjoint societies, the International Congress of Ophthalmologists, the Canadian Army Medical Museum, and the pathological museums of Pittsburgh and McGill Universities, which had been set up in the spacious halls of the Army Medical Museum under the aegis of the International Association of Medical Museums.

THE SITE FOR THE UNIVERSITY OF LONDON.

THE answers of the Chancellor of the Exchequer to a number of questions recently addressed to him in the House of Commons with regard to the possibility of reconsidering the arrangement to use the site at Bloomsbury for the new buildings of the University of London were unfavourable but not absolutely uncompromising. Sir Robert Horne said that the Board of Education was not reconsidering the question of the site, and that therefore the question whether the site at Holland Park could be looked upon as a possible alternative did not arise. Sir Cyril Cobb, who, it may be remembered, was once Chairman of the London County Council, asked whether, if the Senate of the University of London failed within the prescribed time to fulfil the conditions under which it had agreed that the Bloomsbury site should be handed over to the University, there was any intention of advising the purchase, out of money provided from the sale of the Bloomsbury site or otherwise, of the Holland Park or any other site to provide a permanent home for the University. To this Sir Robert Horne replied that the question related to a hypothetical situation with which he was not prepared to deal at present. He admitted, in reply to a question by Mr. A. M. Samuel, that the desirability of relinquishing the scheme for the Bloomsbury site, on the ground that it was not big enough for the purpose, was a matter of opinion, as was also the question whether the Government should act upon the three resolutions passed by the London Education Authority asking that the Bloomsbury proposal should be reconsidered. The matter of opinion and controversy was, he said, whether perseverance with the Bloomsbury site might not, as was suggested, end in disaster.

POST-GRADUATE EDUCATION IN LONDON.

THE Minister of Health, Sir Alfred Mond, has arranged to receive a deputation on July 13th to lay before him the present position of post-graduate medical education in London. It will be remembered that the Committee appointed by the then Minister of Health (Dr. Addison) under the Chairmanship of the Earl of Athlone made in substance two recommendations; one was that an institute or college of hygiene should be established in London. This has been made possible by the munificent gift of the Rockefeller Foundation, aided by the promise of the Minister of Health to make an annual grant of £25,000 for upkeep. A site has been selected and other arrangements are in progress. The other recommendation was for the institution of a post-graduate medical school to serve as a centre of a great teaching organization in which the special hospitals of London, the Poor Law infirmaries, and the medical schools, with their clinical units and research departments, would all find their place. It advised that as an integral part of the organization there should be a bureau or central office controlled by a committee of management and providing a library, a hostel, and all things necessary to afford full facilities for social intercourse. Nothing has been done to advance this second recommendation, and it is on this point that the deputation intends to make representations to the Minister. The members of the deputation will include the President of the Royal College of Physicians of London (Sir Humphry Rolleston), the President of the Royal College of Surgeons of England (Sir Anthony Bowley), the President of the Royal Society (Sir Charles Sherrington), the President of the Fellowship of Medicine (Sir George Makins), Sir Berkeley

Moynihan, Bt., Sir Robert Jones, Sir R. H. Luce (Chairman of the Committee of the British Medical Association on Post-graduate Education), Sir S. Russell-Wells (until recently Vice-Chancellor of the University of London), Dr. George Blacker (Dean of University College Hospital Medical School), and Dr. Charles Buttar.

THE GLASGOW ANNUAL MEETING.

THE attention of members who intend to be present at the Annual Meeting of the Association in Glasgow is directed to the forms for "Notification of attendance" at the annual meeting and at the annual dinner, which appeared in the SUPPLEMENT of June 3rd, p. 207. These forms should be filled in and sent to the Honorary Local General Secretary, British Medical Association Annual Meeting, 22, Sandyford Place, Glasgow, as soon as possible. Those who wish accommodation secured for them should consult the list in the present issue, and communicate directly with the Secretary of the Hotels and Lodgings Committee, Dr. James Hendry, 4, Clifton Place, Glasgow, W. We are asked to state that the local office-bearers of the Section of Ophthalmology desire to entertain the members of the Association attending this Section at luncheon in the Central Station Hotel on Thursday, July 27th, at 1 p.m. It will be a great convenience if members who are likely to be present at the meetings of the Section of Ophthalmology will inform the Honorary Local Secretary of the Section, Dr. W. H. Manson, 17, Royal Terrace, Glasgow, W., as soon as possible, so that some idea of the number likely to be present can be obtained.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Senior Surgeon Commanders R.N.

LIEUT.-COMMANDER KENWORTHY asked, on June 27th, whether the attention of the Parliamentary Secretary to the Admiralty had been drawn to the position of certain senior surgeon commanders of the Royal Navy, as a result of the awarding in the year 1919 of a 50 per cent. increase in pay and pension of officers; whether surgeon commanders who were over 50 years of age at the time of this increase now found themselves entitled to a pension less than 10 per cent. greater than the old rate, though by age and length of service they had earned up to 50 per cent. increase. Commander Eyras-Monsell, in a written answer, stated that the position of these officers had already come under the notice of the Admiralty. The Halsey Committee, on whose recommendation the changes made in the rates of retired pay in 1919 were based, did not propose an all-round percentage increase in the rates, but aimed at assimilating, as far as possible, the rates in the various branches, and with this object laid down a uniform scale of retired pay for all officers of the relative rank of commander, including surgeon commanders. On this scale the rate of retired pay was subject in each case to a maximum of £600 per annum. As the maximum obtainable by a surgeon commander under the old regulation was £547 per annum, the rates for certain surgeon commanders under the new regulations were increased by less than 10 per cent.; and the percentage increase generally was smaller than that in other branches where smaller maximums were previously in force. Such a difference, however, was inherent in any scheme which had for its aim the assimilation of the conditions in various branches, and while therefore some officers might have benefited more than others by the changes made, the Admiralty did not think it desirable to make any modifications in the scheme in order to meet the case of particular classes of officers. (This matter is discussed in a leading article at p. 52.)

National Health Insurance Bill.

The report stage of the National Health Insurance Bill was taken in the House of Commons on July 3rd.

On Clause 1 the Minister of Health, Sir Alfred Mond, at the instance of Major Mackenzie Wood, explained how it was that the proposed transfer of cost from the Treasury to insurance funds included not only the higher cost of medical benefits, but also some administrative expenses. As a matter of fact, the cost of the central administration had been reduced by no less than 3d. a head. The cost of the Insurance Committees up to now had been partly borne by the Treasury and partly by the approved societies. In 1920-21 the total cost, including the cost of the Central Index Scheme, was about 7½d. per insured person per annum, made up of 4d. from the

societies and 3d. from the Exchequer. In 1921-22 the cost was about 7d., of which 6d. was raised from the societies and 1d. from the Exchequer. Under the Report of the Geddos Committee it was proposed to abolish the Central Index Scheme and that the Exchequer grant for this purpose should cease. But the approved societies found the Central Index of great value. That was all the money that was being found; it amounted to about 7d. a member. He had pointed out that the cost of administration for the coming year was estimated at 63d.

On Clause 5, applying the bill to Scotland, Major Mackenzie Wood said the effect of the clause was that insured persons in Scotland had to pay more than those in England; the transferred figure in the case of Scotland being 2s. 9d. against 2s. 4d. in England. Including administration for medical benefits, Scotland was going to pay 2s. 11d., whereas England was going to pay 2s. 6d. including administration, and Wales 3s. 1d. He had thought the fundamental principle of the whole scheme was a flat rate.

Sir Alfred Mond said the difference was one of the first effects of the Scottish Home Rule movement. When the Act of 1918 was passed Scotland, as well as Wales, insisted on having separate benefit funds. The medical payment for doctors in Scotland and Wales had always been more than in England, for the simple reason that the population in those countries was more scattered and sparse and there were greater mileage rates. There had never been a flat rate in the sense indicated by Major Wood. The State had borne the difference between the rates in England, Scotland, and Wales. When that grant came to an end the alternatives left were either that poorer people in the sparsely populated districts in the Highlands or in Wales should have no medical treatment, or much less adequate treatment than they now received, or there must be a reduction in the mileage rates in England because there can be no pooling for England, Scotland, and Wales for medical benefit. The idea, no doubt, that Scotland could not indent on the English Fund was a novelty, but under the Act of 1918 Scotland insisted on having a separate benefit fund. Therefore either the medical profession in Scotland must come under an arrangement whereby they would receive less money or the patients receive less benefit.

In the course of further discussion, after speeches by Mr. Adamson and Mr. Hogge, Sir A. Mond pointed out that the bill did not affect the contract with the doctors. The bill altered the payment from the Treasury of a certain part of the medical benefit to the societies.

Mr. Rhys Davies again brought up the question of the position of approved societies in regard to agreements with the doctors, and asked for a further statement. Sir A. Mond replied: "On the second reading I made a very full statement on this question and also in Committee upstairs. When I made this arrangement with the approved societies I gave them clearly to understand that they would be consulted in the fullest sense before the Ministry entered into any further arrangement with the medical profession, and I wish now to repeat this statement. Most certainly the approved societies will be taken into consultation."

The bill was afterwards read a third time.

The Finance Bill.—In Committee on the Finance Bill, on June 28th, the Chancellor of the Exchequer informed Mr. Rose, who had moved a new clause, that originally only those entertainments the whole proceeds of which were given to a charity were exempt from the duty, but that had been modified to the effect, that where not more than 20 per cent. of the proceeds had been spent upon expenses the entertainment should be exempted from the duty. He recognized that projects for many philanthropic and charitable objects were not pursued because the expenses could not be kept within the present narrow limits of concession. He was therefore willing to increase the amount of allowance for expenses from 20 to 30 per cent. A clause to that effect would be proposed on report. Subsequently the Chancellor of the Exchequer accepted a new clause, moved by Sir E. Bartley-Denniss, providing that Corporation Profits Tax should not be charged on the balance of an association registered as a company with limited liability but without the addition of the word "limited" to its name. The associations affected are Chambers of Commerce, University Colleges, and other educational institutions incorporated under the Companies Act. Such associations make no profit, but sometimes have a balance in hand from their subscriptions which the Inland Revenue authorities have sought to regard as profit.

Voluntary Hospitals Grants.—Sir Alfred Mond, on June 27th, in a written answer, gave a list of grants approved by the Voluntary Hospitals Commission up to June 17th, 1922. The following grants have been allocated to the teaching hospitals of the metropolis: Guy's £6,920, King's College Hospital £10,000, the London Hospital £10,000, the Middlesex £13,220, the Royal Free £12,000, St. Bartholomew's £5,665, St. Mary's £6,580, St. Thomas's £5,350, University College Hospital £12,000. The larger grants to other hospitals in London include £4,650 to the East London Hospital for Children, £5,780 to the Great Ormond Street Hospital for Sick Children, £4,000 to the Prince of Wales's General Hospital, Tottenham, £3,500 to Queen Charlotte's Lying-in Hospital, £5,480 to the Royal National Orthopaedic, £11,000 to the Royal Northern, £3,500 to the West London, £3,400 to the Hampstead General Hospital, £3,310 to the London Temperance Hospital, £2,270 to the Miller General Hospital, £2,250 to the Queen's Hospital for Children, and £2,000 to the Victoria Hospital for Children. The larger grants to provincial hospitals include £10,000 to the Sheffield Royal Infirmary and £7,650 to the Sheffield Royal Hospital, £8,500 to the Manchester Royal Infirmary, £8,000 to Birmingham General Hospital, £3,350 to Bristol Royal Infirmary, £2,925 to the Derbyshire Royal Infirmary. The Minister of Health added that the Commission was anxious that hospitals in the provinces should expedite the presentation of their claims.

The Cases of Ronald True and Jacoby.—On the Home Office vote, on June 29th, Mr. Shortt replied to further criticism as to his interpretation of his powers under the Criminal Lunatics Act, 1883, in the case of Ronald True. He maintained that there was no question of the certificate of a doctor upholding the verdict of a jury. The verdict of the jury stood. If True were to become sane to-morrow he would go back to prison, and there was nothing in the law to prevent his being hanged. The Home Secretary again insisted that no discretion was open to him in regard to the course to be taken. Incidentally Mr. Shortt referred also to the case of Jacoby, to correct several misapprehensions. Jacoby had been described as a young man of seventeen. He was three weeks off nineteen. It had been said that no trouble had been taken to find out whether he was insane. That was not so. He was most carefully and thoroughly examined in Brixton Prison by a very highly experienced prison doctor who was one of the chief witnesses certifying to the insanity of True. Dr. East gave the Home Office a most carefully prepared report, certifying that Jacoby was absolutely sane and above the normal intelligence. Those responsible for his defence went to a well-known medical expert, one of the chief of those who gave evidence that True was insane. This doctor refused to say anything in evidence except that Jacoby was perfectly sane. That was what happened before the conviction. Afterwards Jacoby was examined for a third time—at the instance of the Home Office—by a highly experienced doctor who absolutely confirmed what the other two doctors said.

Pensioners.—Mr. Macpherson informed Mr. Gilbert, on June 29th, that during the years 1920 and 1921 the approximate number of pensioners was as follows: Men, 19,500; widows, 16,000. On the same day Mr. Macpherson supplemented answers previously given as to the limitation of special diet allowed to pensioners. Additional allowances for special diet had not (he said) been withdrawn from pensioners suffering from tuberculosis or diabetes. The allowance was, indeed, expressly continued in those cases by the new regulations when the rate of pension or allowances and other circumstances justified a grant. The allowance was not provided for by the terms of the warrant, and had never been attached to any class of pensioners. Hence no breach of faith was involved in a modification of the regulations. Mr. George Barker asked, on July 4th, whether the Minister of Pensions was aware that the Abertillery and district local committee had passed a resolution expressing alarm at the apparent tendency of medical officers of the Ministry of Pensions to certify men as fit for work, and as not requiring treatment after the pensioners' panel doctors had certified them as unable to work and in need of treatment. Major Tryon said the resolution appeared to have been passed under a misapprehension. Medical officers of the Ministry were required only to certify whether or not a man needed a course of special treatment, and whether he would in consequence of that treatment be unable to work, and would therefore become eligible for allowances under Article VI of the Royal Warrant. The question whether in any individual case the man needed special treatment which it was not within the competence of the insurance practitioners to give was, and must be, entirely one for the judgement of the medical officer of the Ministry who examined the man. This Ministry had no reason to doubt that the instructions in force provided for every man duly receiving the treatment necessitated by his case in accordance with the provisions of the Royal Warrant.

Indian Medical Service.—On June 27th Mr. Hogge asked the Under-Secretary of State for India whether he would consider the advisability of putting the Indian Medical Service on terms of equality with regard to pensions and commutation with members of the Indian Civil Service. Earl Winterton replied that officers of the Indian Medical Service were not alone affected, and promised to consider the whole matter. He returned a similar reply to Dr. Framantle, who asked whether the difference would be remembered between Europeans and Indians in regard to attendance upon white patients.

The Supply of Chemicals.—Dr. Murray, on June 19th, asked the President of the Board of Trade whether in view of the statement by the Dean of the Faculty of Science, in University College, London, that certain chemicals were unobtainable in this country, and had to be imported from Germany, and duty paid on them, he would consider the expediency of seeking powers to exempt such chemicals from the operation of the Safeguarding of Industries Act. Mr. Baldwin said that his attention had not been called previously to this particular statement, but he was aware that certain chemicals were not at present manufactured in this country, a fact which was one of the main reasons for the Safeguarding of Industries Act.

Short Notes.

The Lords amendments to the Infanticide Bill, which was originally called the Child Murder (Trial) Bill, were considered in the Commons on June 30th, and were accepted. The bill was introduced in the Commons by the Labour party, and was in charge of Colonel Wedgwood.

The Local Government and Other Officers Superannuation Bill.—Sir H. Nield, on June 30th, moved the third reading of this bill, which was agreed to without division. Its objects were explained at the earlier stages.

The Minister for Education has found it possible to remove in nearly every case the restriction on the number of defective children who may be sent to existing special schools by local education authorities. A new circular is to be issued to these authorities in a few days.

In reply to a question as to the traffic in cocaine, Sir John Baird (Under-Secretary for the Home Department) has stated that he hoped before long to introduce a short bill increasing the penalties which might be imposed under the Dangerous Drugs Act.

NINETIETH ANNUAL MEETING of the British Medical Association, GLASGOW, 1922.

THE GLASGOW SCHOOL OF MEDICINE.

THE Glasgow School of Medicine may be said to have arisen at a very definite date (1599), and to have been founded by one definite personality—Peter Lowe. At the close of the sixteenth century Glasgow was a town of about 7,000 people, holding only about the eleventh place of importance amongst Scottish towns.

It was probably an insanitary town, not worse than others at the time: its houses built of wood and roofed with thatch; its drainage system consisting of primitive gutters or syvers in the streets; frequently visited by plague and possessing a persistent outcrop of leprosy. Medical practice was in the hands, in the first instance, of a few physicians trained in the schools of Italy, France, and the Low Countries; then there was a fairly large body of barber-surgeons, the general practitioners of the period, not banded together in a corporation, as in Edinburgh and London; then there were also a few barbers who practised surgery only, and, in addition to these, a horde of charlatans, pretenders, sellers of simples, and mediciners of all sorts.*

THE FOUNDING OF THE FACULTY OF PHYSICIANS AND SURGEONS.

In 1598 the Kirk Session urged the Town Council to institute some means whereby the skilled and unskilled practitioners of medicine could be distinguished. In April of the following year the Council appointed a committee (how curiously was that method of getting out of a public difficulty in vogue even then!), three bailies, three city ministers, and three university officers, "with other men skilled in the art to examine for the futuro those who practised in the town." It is probable that the influence of Peter Lowe was at the back of all this. He certainly found means of making some kind of representation to King James VI. The king—it was he who a few years later became James I of England—granted in November, 1599, letters under the Privy Seal empowering Peter Lowe and Robert Hamilton "to examine and try all who professed or practised the art of surgery to license according to the airt of knowledge that they shal be found waird to exercise those whom they judged fit and to exclude the unqualified from practice with power to fine those who proved contumacious." The Visitors, as Lowe and Hamilton were called (the Visitor is still the title of the Vice-President of the Royal Faculty of Physicians and Surgeons), reported to the city magistrates cases of poisoning or violent death, and excluded from the practice of medicine those who could not produce a testimonial from a famous university where medicine was taught. Associated with them was William Spang, an apothecary in Glasgow, who assisted in the regulation of the sale of drugs, especially poisons. Those licensing powers were strictly maintained, and extended far beyond the city to the baronies of Lanark, Renfrew, Dunbarton, and the various divisions of Ayrshire. Thus was created in 1599 the Faculty of Physicians and Surgeons of Glasgow. It is a curious fact that in Glasgow the two great branches of the profession were in those early days, and still are, associated together in one corporation, differing from the practice in Edinburgh, London, and Dublin, where physicians and surgeons are organized in different colleges.

PETER LOWE.

Maister Peter Lowe was a Scot whose early manhood was spent abroad. He saw service in France and Flanders, and was surgeon-major to the Spanish regiments at Paris for two years. He published in London, in 1595, a book on the

Spanish sickness. He came to Glasgow probably in 1598 and was town's doctor, for there is a record in the minutes of the Town Council of March 17th, 1599, that certain sums of money were to be paid to him for attending the poor of the town. He had been so long away from the country that when he returned he was possibly unaware of the changes in the Church government which had taken place and the introduction of the ansterities of Calvinism. At all events he was

for some offence sentenced by the Presbytery of Glasgow to stand "on the pillar." The offence must have seemed trivial, for the doctor paid no attention to the command of the clerics, apparently treating the whole matter as a jest. The Presbytery, however, was in no joking mood, for he was condemned to stand two Sundays on the pillar and pay his fine as well to the "thesaurer" of the kirk. Peter Lowe was probably the first to write a textbook on *Chirurgie*, which was published in London in 1597. He claimed to belong to the College of Sworn Master Surgeons of Paris, the members of which were known as "Surgeons of the Long Robe," to distinguish them from the barber-surgeons, who were "Surgeons of the Short Robe." Lowe died in 1612. His tombstone can still be seen on the south wall of the cathedral churchyard. It is the property of the Royal Faculty of Physicians and

MAISTER PETER LOWE.
(From the portrait at the Royal Faculty of Physicians and Surgeons.)

Surgeons of Glasgow, and bears the following quaint inscription:

"Stay, Passenger, And, View, This, Stone
For, Under, It, Lyes, Such, A, One
Who, Chaired, Many, Whill, He, Lived
Soe, Gracious, He, Noe, Man, Grieved
Yen, When, His, Phisicks, Force, Oft, Failed
His, Pleasant, Purpose, Then, Prevailed
For, Of, His, God, He, Got, The, Grace
To, Live, In, Mirth, And, Die, In, Peace
Hevin, Hes, His, Soul, His, Corps, This, Stone
Sigh, Passenger, And, Soe, Be, Gone

Alh Me I Gravel Am And Dust
And To The Grave Desend I Must
O Painted Piece Of Liveing Clay
Man Be Not Proud Of Thy Short Day."

EARLY DEVELOPMENT OF THE MEDICAL SCHOOL.

During the seventeenth century the Faculty of Physicians and Surgeons gradually developed some kind of organization and made its influence felt in the city. It retained the whole control of licensing of practitioners and surgical apprentices such as it was, and indeed more than two centuries afterwards, when medicine and surgery had long been recognized as subjects of study and examination in the University, the

* Previous articles, on the City and University of Glasgow and its medical institutions, have appeared in the *BRITISH MEDICAL JOURNAL* of December 3rd, 1921, p. 961, January 7th, 1922, p. 29, February 11th, p. 242, April 22nd, p. 649, and June 3rd, p. 683.

Faculty obtained a decision from the Court of Session that without examination and licence by them the holder of a university degree was not entitled to practise surgery within the fairly wide territory of the Faculty.

In this century the University had for itself begun to recognize the importance of the study of medicine. In 1637 Robert Mayno was elected Professor of Medicine. His duty was to "teach and publickly lecture of medicine in the said Colledge once or twyse everie week, except in the ordinar time of vacancee." But in 1642 a Commission of Visitation of the General Assembly found that the profession of medicine was not necessary for the college in all time coming; but allowed Mayno to continue to be professor during his life. He died in 1646, a year in which there was a virulent outbreak of plague, so severe that the University migrated in a body to Irvine on the Ayrshire coast. In that year the plague-stricken people were deported to the Muir lands of Sighthill in the northern part of the city, where they were visited by John Hall, the principal surgeon of the day, a man plainly built in heroic mould, carrying out his medical duties with the courage of all medical heroes.

It is not till the first half of the eighteenth century that we come again upon the names of men who built up the Glasgow School. In 1714 Dr. Johnstoun was appointed by the Faculty of the University to the revived Chair of Medicine. With the beginning of the century the University began to give degrees in medicine, though not to teach the subject. In 1720 a Chair of Anatomy and Botany, two subjects curiously linked, was founded, and Thomas Brisbane was appointed. Brisbane, however, disliked anatomy and would not dissect; he appears to have had no great objection to teaching botany. In 1727, he was ordered to teach anatomy if even ten students tutored—the whole story has a peradventure ring about it—but there is no record that he did so. He gladly handed over these duties to Mr. John Paisley, who taught anatomy for ten years in the Humanity classroom. One of Mr. Paisley's apprentices, William Cullen, was destined to make for himself an everlasting name as the founder of modern medicine, and was to a notable degree the fount and stimulus of the Hunterian inspiration.

William Cullen was born in Hamilton, a county town ten miles south of Glasgow; he was the son of a lawyer, factor to the Duke of Hamilton of that day. After finishing his studies in Glasgow he spent a *Wanderjahr* in a voyage to the West Indies, and on his return pursued his studies in London, and later in the quickly growing medical school of Edinburgh. He began practice in Shotts, and then removed to his native town, and until recently the house in which he practised was standing at the corner of Castle Street and the New Wynd. His reputation spread, and in 1744 he came to Glasgow, notwithstanding the efforts and promise of a laboratory by the Duke of Hamilton. Almost immediately he began to lecture, and these lectures were apparently the first systematic attempt to teach medicine in the city. He broke new ground by discarding Latin and lecturing in English. He lectured on botany, physic, materia medica, and lastly, on chemistry. In 1751 he was appointed Professor of Medicine, an appointment he held but a short time, for four years later he was transferred to the Chair of Chemistry in Edinburgh University. In Edinburgh also he taught medicine, and introduced the epoch-making change of bedside teaching. His most important work was done in Edinburgh, but he had done great and notable work for the Glasgow school: he had set going classes of instruction in medicine, materia medica, botany, and chemistry; he had attracted large numbers of students; he had extended the reputation of the

University amongst professional and scientific men not only in the United Kingdom but also on the continent of Europe. "He was one of the rarest species of the man of science—a masterless master." His influence on William Hunter was profound. They came together when Cullen was 27 years of age and Hunter 19. Cullen gathered the latest publications on medicine and chemistry, made frequent experiments himself, and (most extraordinary of all) kept accurate notes of every case in his practice, a plan adopted, too, by his senior, Smellie, in Lanark.

William Hunter studied both in Glasgow and Edinburgh, and in 1750 Glasgow conferred upon him the degree of M.D. His influence is perpetuated for all time in the Hunterian Museum, a storehouse of marvellous wealth in books, pictures, coins, as well as anatomical and pathological specimens. Sir William Gairdner always began his course of lectures by long quotations and references to Cullen's *Nosology*, for Gairdner regarded Cullen as the opener up of a new era in medicine, as the first to cast aside the old traditions and canons and to teach that the physician was the servant of nature, and that disease must be learned only from direct study of the patient.

WILLIAM CULLEN.

Hunter remained in London. Another friend of Cullen older than he, was Dr. John Gordon, a practitioner in Glasgow, President of the Faculty in 1755. He was friend and correspondent of Smellie. His pupil Tobias Smollett introduced him as "Potion" in *Roderick Random*. Smollett's place with Gordon was taken by John Moore father of the hero of Corunna. He too with Smollett was found in London amongst the Hunterians.

When Cullen and William Hunter dreamed of making Glasgow a great Medical School—Leyden and Edinburgh were the patterns—building the science of medicine on a foundation of chemistry, John Hunter, the greatest of them all—"the Shakespeare of Medicine"—was a rough, harum-scarum, auburn-haired lad, working on the farm at Long Calderwood, ignorant of books, but quick and apt to see and know the things of nature around him.

An Interesting Succession.

Another friend and pupil of Cullen was Joseph Black, of "latent heat" fame: Black was the discoverer of latent heat, but the first suggestions regarding it came from the fertile brain of Cullen. Black succeeded to the Chair of Chemistry in Glasgow when Cullen went to Edinburgh. One of his pupils in turn was James Watt, and so the torch was handed on. Dr. Freeland Fergus has fondly pointed out a most

The Hunterian Homeland.

Associated with that period and to some extent with Cullen himself was a group of men who left a lasting and deep impression on the world of medicine. All were not specially connected with the Glasgow School, but their influence on it must have been felt. It is remarkable that these small villages of the Clyde Valley—Hamilton, East Kilbride, Lanark, Bothwell—should at the same period have produced a group of minds of the highest scientific quality. We have pointed out that Cullen was born in Hamilton. William and John Hunter were born at Long Calderwood in the parish of East Kilbride. Matthew Baillie, nephew of the Hunters, was born in Bothwell. William Smellie, the famous London obstetrician, was a Lanark man and practised there before the desire for wider scope and opportunity drove him south. Hunter was an intimate friend of Cullen, worked as his pupil or apprentice for two years, and it was his intention to practise with him in Hamilton as his surgical partner. But an appointment with Douglas the anatomist proved so enticing that William

interesting succession: Cullen taught Joseph Black; Black taught Thomas Thomson; Thomas Thomson when Professor of Chemistry taught Graham, afterwards Master of the Mint and for some time Professor of Chemistry in Anderson's College; Graham in University College, London, had as a pupil Joseph Lister. Thus the founder of modern medicine is linked *longo intervallo* with the founder of modern surgery. These men all belonged to the Glasgow School and their names are inscribed on the roll of Fellows of the Royal Faculty of Physicians and Surgeons.

Joseph Black.—When Cullen left Glasgow Joseph Black became the dominant figure in the University world. A student of Glasgow University both in arts and medicine, he attracted the notice of Cullen and became his pupil and assistant. His medical course was finished in Edinburgh. In 1756 he succeeded Hamilton as Professor of Anatomy and Botany, and a year later was appointed Professor of Medicine in addition. He succeeded Cullen as Lecturer in Chemistry, and that branch of science permeated all his other teaching. His great achievement in Glasgow was the discovery of latent heat. His experiments were closely watched by other professors and by another man of genius, James Watt, whose workshop was housed in the University grounds. It is in a way a matter of regret that Glasgow lost the great services of Cullen and Black on their successive removals to Edinburgh. When that change came, when Black removed to Edinburgh to succeed Cullen in the Chair of Chemistry, the Lectureship in Chemistry in Glasgow was held by John Robison, about whose name floats a story of another kind. In his youth he had been a midshipman in the Navy and was in the boat in which Wolfe went to inspect some posts before the storming of Quebec. He brought back the story of the great "General repeating aloud nearly the whole of Gray's 'Elegy,' then recently published, and declaring that he would rather be the author of that poem than conquer the French on the morrow." His career did not end as a University lecturer in Glasgow, as he became secretary to Knowles, who was then at the head of the Russian Admiralty, and finished as Professor of Natural Philosophy in Edinburgh University.

Thomas Thomson deserves special mention. He was a graduate of Edinburgh, M.D. in 1799. Before then he had achieved distinction, as he became editor of the *Encyclopædia Britannica* in 1795 when only 26 years of age in succession to his brother. He was the introducer of the oxygen-hydrogen blowpipe and of the system of chemical symbols and chemical equations. He was appointed to the Chair of Chemistry in 1818, and was Physician to the Royal Infirmary for two years only. He was a man of quaint enterprise, and stories are told of him by Dr. Freeland Forgue. He walked all the way from Edinburgh to Glasgow in 1808 to see the Pontine illuminated by coal gas. Once when on a paddle steamer on the Clyde, in the earliest days of steam, he had got hold of a bucket and a rope and went out on the wing of the paddle to draw a sample of the churned-up water after it had passed the paddle. Whatever his idea in making the experiment he seems to have forgotten one factor, for the pull on the bucket made him lose his balance and he was, with some difficulty, saved from a watery and inglorious end. He was popular, as he became the first chairman of the newly organized Medico-Chirurgical Society in 1844.

Thomas Graham brings the story of the Glasgow School down to the middle of the nineteenth century. Though not a doctor he required to become a Fellow of the Faculty to lecture on chemistry to students of medicine. He was the outstanding physicist and chemist of his time. He did not belong to the University but was Professor of Chemistry in Anderson's College. His work on *Diffusion of Liquids* appeared in 1846. In 1837 he was appointed to University College, London, and in 1854 he became Master of the Mint.

THE GLASGOW MEDICAL SCHOOLS.

The University.

At the end of the eighteenth century the University Medical School had a staff of six teachers, a Professor of Medicine, a Professor of Anatomy, and lecturers on chemistry, materia medica, midwifery, and botany. The medical students were nearly 200 in number. The Royal Infirmary had been opened in 1796 and provided an ample field for clinical work. The Napoleonic wars awakened the authorities to the needs of surgery, and in 1815 the Chair of Surgery was founded. The Chairs of Physiology or Institutes of Medicine and of Forensic Medicine were founded in 1839. The close proximity of the University to the Royal Infirmary made it easy to carry out the clinical teaching, and up till the removal of the University to the west end of the city the wards of the Royal Infirmary were crowded with students. To-day University students overflow from the Western Infirmary back again to the Royal Infirmary and to the Victoria Infirmary, in all of which the accommodation is taxed to the utmost, and the distribution is accomplished only by a precise limitation of the numbers admitted to the clinical classes. The story of the University has already been told in a previous article.

The Anderson College of Medicine.

The Faculty of Physicians and Surgeons, as we have indicated, was the licensing body of Glasgow, controlling the apprentices and the general practitioners. It was not a teaching body. In the eighteenth century any extra-academic teaching was occasional only. In 1764 Dr. Andrew Morris, a graduate of the University of Rheims, practised in Glasgow, and lectured on medicine in the Faculty Hall; and Mr. James Monteath lectured on midwifery from 1778 for a few years. With the establishment of Anderson's University, or as it is now called the Anderson College of Medicine, in 1795, extramural teaching became continuous. The founder of the College was John Anderson, M.A., F.R.S. This most ingenious and public-spirited man became at the age of 29 Professor of Oriental Languages, and shortly afterwards Professor of Natural Philosophy. He was the originator of the Mechanics' Institutes, and for forty years gave series of public lectures on experimental physics to the mechanics and operatives in the factories of Glasgow. He

JOSEPH BLACK.

was the inventor of a gun carriage and the introducer of the balloon posts adopted by the French in 1791 in their effort to spread republican propaganda. It was to him that James Watt owed a great debt, as he befriended Watt and encouraged him in his researches and helped the establishment of his workshop in the University grounds. At Anderson's death he left the whole of his property "to the public for the good of mankind and the improvement of science in an institution to be denominated Anderson's University." The scheme for the University was complete, but it became grandiloquent when it was found that the bequest was only £1,000. However, after vicissitudes and hamperings for want of money the school began to prosper and by 1833 had a full curriculum, with more teachers than the University of Glasgow. Anderson's University was housed in a building in George Street, not far from the University of Glasgow. The popularity of the teachers and the variety of subjects induced many University students to take classes there. The classes have for many years been recognized as qualifying for University degree examinations and for the diplomas of the Colleges and Faculty. In 1836 the Medical School was separated from the other departments of work of the Anderson University, and the Technical College, now a magnificent building in George Street, City, the finest of its kind in the world, was established, the Medical School being removed to its present site close to the Western Infirmary.

*The Royal Infirmary School of Medicine, and
St. Mungo's College.*

The removal of the University to the west and the opening of the Western Infirmary was a disastrous blow to the Royal Infirmary. Steps were accordingly taken in 1875 to rehabilitate the Royal Infirmary as a clinical school. The leading spirits in this praiseworthy effort were Dr. John Gibson Fleming, a former president of the Faculty of Physicians and Surgeons, and Mr. William MacEwan, both managers of the Infirmary. They were successful in obtaining a charter which included: "Powers to offer facilities and accommodation for the teaching of medicine and surgery and the collateral sciences usually comprehended in a medical education." At first the school was housed in temporary classrooms, and in 1883 the present commodious buildings were erected, adjoining the Royal Infirmary on its northern side. At a later period, 1889, the Royal Infirmary School of Medicine was converted into St. Mungo's College, the teaching being conducted in the same buildings. In 1912 the connexion of the Royal Infirmary with the University was re-established, when four new professorships—Medicine, Surgery, Obstetrics and Gynaecology, and Pathology—were founded. The association of the Royal Infirmary with the University is still more closely cemented by the appointment of surgeons and physicians of the Infirmary to be University lecturers and examiners. There were other extramural schools in Glasgow in former days—namely, the Portland Street Medical School and the Western Medical School—but these were on the whole short-lived, though serving a useful purpose in their day. The extramural schools of Glasgow have not only possessed teachers of their own of great eminence, but they have also provided an excellent training ground for men who rose to higher spheres in the University. Many University professors first made their name as teachers in these extra-academic schools, and when the time came they carried with them scientific and teaching reputations, the lustre of which was not as a rule dimmed by the more serene and stable atmosphere of the University.

MODERN GLASGOW SCHOOL.

We may now return to consider the Modern Glasgow School. The name that stands out most prominently in the middle of the nineteenth century is that of Lister.

Joseph Lister was Professor of Surgery from 1862 to 1869, when he too, like so many of his academic forebears, yielded to the claims of Edinburgh—strong claims to him, both scientific and social. When he came to Glasgow to fulfil the duties of the Chair of Surgery he was in the anomalous position of having no wards in the Royal Infirmary, a condition of affairs which was not rectified for nearly two years. The story of his surgical achievement needs no repetition—it is sufficiently familiar. The ward in which his great work was accomplished is still extant, and quite a number of his pupils will be found in Glasgow to-day. There can be no doubt that Lister's investigations and discoveries during his term of office in Glasgow completed the discovery of antiseptic surgery. His work later was simply that of amplification and extension: it was in Glasgow, then, that modern surgery was born. In Glasgow the reception of the new ideas in surgery was more cordial and the adoption of the system more ready than probably in Edinburgh and certainly in London. With one exception, Lister's colleagues very soon came to see the true nature of the revolution, as they had been constantly in touch with what Lister was doing and heard his first expositions of the new theory. Besides, a genius like Lister attracted the younger men, and their actively receptive minds saw what a great thing it was and spread abroad the conception.

Assisting at the birth and bestowing infinite fostering care

on these new ideas and practice in surgery, Sir Hector Cameron did much to maintain in Glasgow the work begun by Lister. Gifted with graciousness of manner and the silver tongue of the orator he was specially fitted for the task of advocate of the new surgical faith. A neat operator, an impressive teacher, and a man of unbounded social and professional popularity, Sir Hector held, and still holds, a position deep in the hearts of the Glasgow profession.

Sir George MacLeod, Lister's successor in the chair belonged to a great Scottish family renowned in the Church and in social circles. His commanding presence (his nickname was "The Duke") and firm, impressive, incisive style of teaching are still remembered by many generations of students.

In anatomy Allen Thomson and John Cleland were towers of strength in Glasgow. The Glasgow School has not been regarded even by its alumni as essentially an anatomical school. But it had a great reverence for its teachers of anatomy. Allen Thomson was a member of a family which achieved great distinction: his grandfather was a Paisley weaver, his father became a professor in Edinburgh, his brother a professor in Glasgow, and his son a professor of chemistry in King's College, London. In anatomy he was

well known as one of the editors of *Quain*, and was an early worker in embryology. He will always be remembered as having taken a most active part in the founding of the Western Infirmary.

That massive man, John Cleland, who succeeded him, made deep impressions on all his students, though it is just possible that they failed to appreciate his great capacity as an anatomist. In the subject of obstetrics and gynaecology the Glasgow School claims with pride that the first successful ovariotomy was performed by Mr. Robert Houston, Fellow of the Faculty, whose operation was performed in 1701. A complete account of the operation has been preserved in volume xxxiii of the *Philosophical Transactions*, London, 1733. And again, to Murdoch Cameron belongs the great credit of having made Caesarean section a successful, and now extensively performed, operation.

Another of the great men of the Glasgow School was Dr. William MacKenzie, perhaps the most distinguished ophthalmic surgeon in the United Kingdom of his time. Very shortly after receiving the diploma of the Faculty he went to the Continent, where he spent about

two years, devoting himself chiefly to ophthalmology. In London he became a member of the Royal College of Surgeons, and began to lecture and practise in diseases of the eye. Fortunately for Glasgow, his success was so limited that he returned to the city. In 1824, with Dr. Montenth, he founded the Glasgow Eye Infirmary, an institution which has always played a large part in Glasgow medical life. MacKenzie was a clinician of the highest standard; he was probably the first to give an accurate description of glaucoma, and his observations on sympathetic ophthalmitis proved to be the first clear description of that disease.

Andrew Buchanan is a name which is written in gold in the annals of the Glasgow School. He was Professor of Physiology and also surgeon to the Royal Infirmary for a considerable number of years. He was the first to give a scientific explanation of coagulation of the blood, and his papers on this subject in 1844 attracted attention throughout the world. His rectangular staff for lateral lithotomy is a well-known instrument, and was used for that operation up till quite recently.

When the British Medical Association met in Glasgow in 1888 the presence of W. T. Gairdner, Professor of the Practice of Physic in the University and President of the Association, lent distinction to all its meetings. It is probably true to say that no man of the Glasgow School for the past two generations exercised such a wide influence and directed so

WILLIAM MACKENZIE.

many minds along scientific paths of medicine. Glasgow men of middle age who meet in almost any capacity, social or otherwise, find even now a congenial subject of discussion in Gairdner's personality, his teaching, his philosophic mind, his scientific attainments, even, indeed, his absent-mindedness. The physician to him was first of all a naturalist. That, indeed, was the subject of one of his many addresses. His "Plea for Thoroughness" was in no sense a trite commentary on slipshod methods but was an earnest appeal for painstaking, careful, detailed investigation. "Old G." was in all essentials the "beloved physician." Gairdner was the first medical officer of health of the City of Glasgow; indeed it is almost certainly the case that he was the inventor of the whole idea of the special department of public health. His work in this department was characterized by energy and skill and imagination. Associated with him was Dr. J. B. Russell, under whose administration the public health department took first rank in the world. These two men instituted the fever hospitals, an efficient sanitary department, and the city improvement schemes, the result of which has been that Glasgow has been amongst the highest in the records of public health.

Closely associated with Gairdner and of like minds to him were Dr. Joseph Coats, the first Professor of Pathology in the University, and Dr. James Finlayson, a man of enormous clinical ability, whose learning in the bibliography of medicine was the wonder of all who came in contact with him. The Glasgow School of Pathology began to make a name for itself under Coats. He possessed the gift of surrounding himself with assistants and pupils fired with his own zeal. From the days when some of these left Glasgow to fill chairs of pathology in other schools there has been, under his successor, Robert Muir, a constant outgoing stream of pathologists from Glasgow to the medical schools of the Empire.

The School of To-day.

What the characteristics of the Glasgow School of Medicine are at the present day the visitors to Glasgow must decide for themselves. The School is fortunate in having Sir Donald MacAlister, the President of the General Medical Council, as Principal of the University. Sir Donald MacAlister's learning and accomplishments and great influence are directed to one object—the increasing glory and expansion of the University of Glasgow. As a physician himself he has more than a warm heart to the Medical School, and his activity is felt in many spheres outside the academic walls.

Of Sir William MacEwen, the President of the Association, we do not presume to make an estimate. Let it be said that Glasgow is more than fortunate in possessing as its surgical head the greatest surgical genius of his day. From the time when he became surgeon to the Royal Infirmary as a very young man up till now his scientific enthusiasm has not abated nor his powers of investigation diminished. Perusal of his works on Osteotomy, Hernia, Pyogenic Diseases of the Brain, the Growth of Bone, leaves the impression on the mind that the last word has been said—that these works are classical.

What, then, will the British Medical Association find when it comes to Glasgow? A large, flourishing, virile school; a body of keen, enthusiastic teachers; students eager and anxious, interested in the profession they hope soon to enter, mingling in suitable proportions the academic and social sides of their life.

The Glasgow School makes large claims. Though Cullen did not begin clinical teaching actually in Glasgow, the clinical method and the essential foundation of medicine in the science of chemistry were established by him in his practice in Hamilton, and so the idea of clinical medicine came from Glasgow. Then Glasgow claims the birth of modern surgery through Lister. She claims the introduction of scientific midwifery through Smellie of Lanark. She claims the modern development of public health through Gairdner and J. B. Russell. And, last of all, she claims that the masters and pupils of the School of to-day are in no way behind their fathers in capacity for labour and for scientific investigation, in generous large-mindedness and imagination, and in devotion to what, after all, still is the noblest of the professions.

NOTE.—The writer of this article desires to express his indebtedness to Coutts's *History of the University of Glasgow*, to the *Memorials of the Faculty*, Freeland Fergus's *History of the Glasgow School of Medicine*, and to the *History of Glasgow*, published by Dr. Christie for the centenary meeting in 1888.

England and Wales.

SANITARY REGULATIONS FOR THEATRES AND MUSIC HALLS.
THE Theatres and Music Halls Committee of the London County Council has been overhauling the regulations of the Council with regard to the construction of theatres, music halls, and other places of public entertainment, including cinematograph exhibitions. The regulations are chiefly directed to minimizing fire risk, but they include certain provisions for the health and convenience of the audience and of the performers and staffs. A new regulation has been inserted laying down the sanitary accommodation required in different classes of premises, according to the number of persons accommodated. Automatic flushing apparatus of a pattern approved by the Council must be installed, and all the floors of the sanitary apartments and the lobbies approaching them must be constructed of impervious material and sloped to a drain. It is also required that ventilation direct to the outer air shall be provided to the corridors in the dressing-room block, that permanent ventilation shall be provided to dressing rooms by means of flues built into the brickwork, and that dressing rooms shall be adequately heated and a supply of hot water provided. A new requirement is that natural lighting by means of windows and skylights must be provided in the auditorium and, where practicable, in all other parts of the premises, though during performances these may be obscured by curtains or shutters. A draft set of regulations dealing with the general ventilation of the auditorium, as distinct from the rooms for the performers and staff, is still under consideration.

ST. PAUL'S EYE HOSPITAL, LIVERPOOL.

The annual report of the hospital shows how successful the treatment of ophthalmia neonatorum has been during the past year. One case only, out of 222 infants treated for this disease, resulted in blindness. During the war period ophthalmia neonatorum increased, and this is the first decrease since 1915. The number of out-patients was 6,763, and it is noteworthy that there were 919 removals of foreign bodies from patients' eyes. Financially, during the past year the committee regrettably draws attention to the maintenance fund. This has been depleted to the extent of £337. A ladies' committee has been most useful in restricting expenditure; nevertheless, as the Lord Mayor pointed out, increased support was essential, and he looked forward hopefully to the immediate future when the finances of the Liverpool hospitals would be placed, each and all, on a satisfactory basis.

THE HEALTH OF WALLASEY.

This growing township, according to the annual report of the medical officer of health, Dr. T. W. N. Barlow, is in a salubrious condition. The death rate, 10.7 per 1,000, was the lowest on record. With regard to infant mortality, 59 per 1,000 births—this also was the lowest on record. Twenty years ago infantile mortality varied all over the country between 130 to 200 per 1,000 births, and 100 per 1,000 births was almost regarded as the irreducible minimum. In the case of Wallasey this irreducible minimum had itself become nearly one-half. The total number of births amounted to 1,640. The last census (1921) gave the population of Wallasey as 90,721.

Scotland.

PROPOSED INTERNATIONAL BOWLING MATCH AT THE GLASGOW MEETING OF THE BRITISH MEDICAL ASSOCIATION.

IN the SUPPLEMENT of the JOURNAL for June 17th it was stated that the Entertainments Committee proposes to have an International Bowling Match, North v. South, on the Willowbank Bowling Green on Thursday, July 27th, and those desiring to take part in the game were requested to send their names, with a note of their experience as match players, to Dr. William Snodgrass, 11, Victoria Crescent, Glasgow, W. The game is timed to take place between 2 and 4 p.m., thus allowing members to attend the morning Section work, have lunch and two hours' play, and thereafter be taken in a motor conveyance to the Municipal Buildings to attend the civic reception by the Right Hon. the Lord Provost and magistrates of Glasgow. So far only four members have

signified their intention of playing for the South, and it is hoped that a larger number will take part in the game so as to give it a more representative character. Notification of intention to play is requested at once, so that arrangements may be completed. Bowls will be supplied to those who do not prefer to bring their own.

GLASGOW HOSPITAL FOR SICK CHILDREN.

The annual report of the Royal Hospital for Sick Children, Glasgow, states that 12,583 patients were treated during 1921, an increase of 2,876 on the previous year. The number of in-patients was 4,749. X rays were used for diagnosis or treatment in 4,555 cases in 1921, as compared with 1,899 cases in 1920, and, of the total number of cases admitted, 1,679 were infants under one year. At the country branch of the hospital at Drumchapel 339 patients were treated, the number of patients under treatment being 29, 14,769 new patients received treatment, the average attendance for each day being 147. The total expenditure for the hospital, the country branch, and the dispensary was £34,051, and the ordinary income was £21,227, so that there was a deficiency on the ordinary income of £12,824. An extraordinary income of £17,773, which included several large grants which will not be repeated, enabled the hospital to have a balance on the year of £4,949, but the deficiency of over £12,800 in the ordinary income indicates a position which requires careful consideration by the people of Glasgow and the west of Scotland.

APPOINTMENTS TO GLASGOW HOSPITALS.

A number of important appointments have been made recently to various hospital staffs in Glasgow.

Western Infirmary.—Fargnhar Macrae, M.B., C.M., visiting surgeon; Hugh Morton, M.D., F.R.F.P.S.G., assistant physician; Lawrence T. Stewart, M.B., Ch.B., assistant medical electrician; D. K. Henderson, M.D., F.R.F.P.S.G., consulting physician for mental diseases; G. Maitland Ramsay, M.D., F.R.F.P.S.G., consulting ophthalmic surgeon.

Victoria Infirmary.—John L. Howie, M.D., surgeon, and Alexander Strang, M.B., Ch.B., assistant surgeon for diseases of ear, nose, and throat.

Correspondence.

STERILIZATION OF MENTAL DEFECTIVES.

SIR,—The subject of sterilization of the so-called dysgenic classes is one that recurs periodically, and the same family histories are continually being brought forward with a refreshing sense of originality year after year. The person who advocates sterilization assumes, first, that we know exactly how heredity acts, and, secondly, that by sterilization we should only prevent the production of the unfit. The first assumption we need not discuss, as the statement carries its obvious denial. The second assumption is not based upon anything more than a general impression, added to the well-known histories of such families as the "Jukes" and the "Kallikaks": these are, of course, very striking, but a great many more family histories require to be examined in detail, before drastic, coercive action such as sterilization becomes the conclusion of the syllogism.

As an example I will quote one carefully examined series of families mentioned by Lange (Denmark). Forty-four families supplied seventy mental patients to his institution; the most numerous represented had four members, the majority only one, affected. In the ascending family lines of these patients, with their collateral branches, for a few generations, some 400 showed mental symptoms, varying from "excessive nervousness," "gloomy disposition," "variable temper," "excitability," and "eccentricity" to definite insanity. These same forty-four families, however, also produced two cabinet ministers, one ambassador, three bishops, eight prominent clergymen, three generals, several other high military officers, three admirals, several other high naval officers, three members of the High Court of Justice, two headmasters, two directors of well-known institutions, eight hospital physicians, nine university professors, at least twenty-three holders of academic doctorates, and a large number of eminent officials, business men, members of Parliament, physicians, teachers, and others of value to the community. Had, therefore, these mentally oblique persons in the earlier generations been sterilized, as recommended (and the parents of the defective

as well as the defective must be sterilized), we should have lost not only the 400 mental patients but also a long array of highly valuable members of the community.

The statement that "sterilization of both sexes is carried out with great benefit in fifteen States in America" is, I believe, not correct. Recent information indicates that twelve States have limited sterilization laws on their statute books. In Indiana the revulsion of public feeling was so great that the law died a natural death; in some other States the law was promptly vetoed; in Washington it is a punitive measure for habitual criminals, and has never been put into force; in California it has been carried out more freely than elsewhere (634 insane, one criminal); the results are not known. In Connecticut, New Jersey, New York, North Dakota, and Kansas the law, though in existence, has practically not been made use of at all; in Michigan it has been applied to a few insane; in Iowa the law refers to a very large number of different classes of people, including "drug-takers" and "syphilitics" (Popenhoe and Johnson): no operation has, however, taken place under the Act.

I would conclude by quoting the cautious statement of Goddard (to whom we are indebted for the history of the Kallikak family):

"At best sterilization is not likely to be a final solution of the problem. In using it we must realize that the first necessity is the careful study of the whole subject, to the end that we may know more both about the laws of inheritance and the ultimate effect of the operation."

—I am, etc.,

JAMES R. WHITWELL, M.B.,
Medical Superintendent, St. Audry's Hospital,
Milton, Suffolk.

July 3rd.

SIR,—It is much to be hoped that Lieut.-Colonel A. E. J. Lister's letter in your issue of July 1st (p. 29) will draw very serious attention to this subject. Anyone working upon mental deficiency cannot but be impressed by the constant menace to society and to the nation from those defectives not actually under institutional care. It is certainly not generally realized how great an increase in our defective population is permitted under present conditions, and the "financial stringency" now obtaining will be felt in the near future by an increased burden. If Gloucester's example were followed by other counties the outlook would indeed be black. One hopes that Mr. Davies may yet be able to impress his constituency with the seriousness of the position. Unfortunately it does not follow that all Gloucester defectives will remain in their own county.

Colonel Lister's plea for sterilization is thoroughly sound. It is conceivable that individually it might sometimes result adversely as regards general health, but the State has to be considered as well as the individual. Moreover, endocrinologists will have something helpful to say as to whether, for instance, the endocrine balance would suffer as much as it is apt to at the menopause. It would meanwhile be of the greatest interest to have reports from the medical officers of health of those States of America who have given the lead as to these and other results.

I very much hope that Colonel Lister's letter will result in widespread discussion.—I am, etc.,

CLAUDE A. P. TRUMAN,
Medical Adviser on Mental Deficiency, Devonshire
County Council.

July 2nd.

SIR,—*"Rem acu tetigit"* is, in my opinion, the deduction reached by Colonel Lister in his letter of June 22nd (p. 29) for these reasons:

1. I have practised the art of medicine for fifty-one years, and have witnessed for three generations the deplorable results of the procreative powers of mental defectives.

2. As a magistrate of forty years' experience in three counties I have at times been exercised in dealing with cases in which it was evident the delinquent had more or less mental obliquity to estimate what portion of the offence was due to the mental condition, and it is a matter for congratulation that such cases are to-day better understood, and that medical evidence can be obtained to consider which is the predominant factor—mental disease or crime?

3. As a visiting magistrate at a large gaol I know that many of the prisoners had hereditary mental defects which explained why they were chronic criminals. Here again it is a happy sign that the authorities recognize the fact, and that any recommendations of the prison medical officers are fairly considered.

4. As a member of a county hospital for mental cases I have learned that the mental condition of the parents of certain inmates was the origin of their present detention.

5. As a member of a County Mental Deficiency Committee since the passing of the Act, 1913, extensive and intimate experience has burned into my brain that no mental deficient should by law be allowed to be a parent.

6. During the war as commandant of two large military convalescent hospitals I realized that the so-called shell shock could often be traced to family mental weakness.

To-day it may seem a relic of barbarism to advocate "the survival of the fit." Still, I am certain the present benign policy in the treatment of the young mental deficient is not only wrong on eugenic principles but is an unjustifiable expenditure of public money, imperial and rate-paid, and if the desire is to obtain an A1 population it is a mistake; all possibility of any mental defectives becoming parents must be prevented. The present feeble segregation is childish as a remedy. If the segregation were effectual the absolute sexual negation would be cruel; effectual sterilization is the only real remedy. I know a village in which a mental defective impregnated four young girls.

In dealing with sterilization of mental defectives let us put all humbug on one side and go to the rock bottom of so many of the causes of hereditary disease and so legislate that everyone who is so unfortunate as to acquire syphilis shall at once on proof be sterilized; had the procedure been in vogue how many fewer mental defectives and tuberculous people would now have.

In your issue of July 1st two admirable reports ("The causes and prevention of foetal death" and "Foetal death") conclusively prove that syphilitic parents are a national danger. These alone are sufficient evidence that Colonel Lister's letter is on right lines.—I am, etc.,

Folkestone, July 3rd.

P. BROOKE GILES.

AMAAS OR ALASTRIM.

SIR,—The application of special terms even to homogeneous groups of disease which differ only in severity from an acknowledged disease entity such as small-pox would confuse and not aid our nosology. If amaas and small-pox do not resemble one another in their principal features, then amaas is a separate entity, as Dr. Garrow maintains it to be, and it is entitled to a distinctive designation other than "small-pox of a mild type."

According to Bristowe, the real disease is not merely the organic lesion but a "complex," the "sum total of morbid changes in both function and structure."

If we compare small-pox and amaas according to this definition it must be confessed they differ in totality more in degree than in kind. The above definition, however, does not cover the whole case entirely, for it is probable, though not demonstrable, that there is a difference between the virus of small-pox and the virus of amaas, for on some such hypothesis alone can the marked contrast in severity and the other observed differences of their respective manifestations be explained.

Vaccinia teaches us that the virus of small-pox is susceptible of variation or mutation. By passage through a calf or other animal the virus of small-pox is changed into the virus of vaccinia. As the etiological agent is not known the actual changes cannot be demonstrated, yet all would allow that vaccinia is a different disease from small-pox.

If one could imagine a person covered to the same extent with vaccinia eruption as he would be if suffering from an attack of small-pox, it might conceivably be difficult to believe that the case was not one of small-pox but was a different disease—namely, vaccinia—and that the difference was due to a modification of small-pox virus.

In my original paper, which appeared in the *Lancet* of May 7th, 1904, after contrasting amaas with the infectious diseases of lascars and varioloid varicella described by Dr. Browlee and Thomson and Dr. Izett Anderson, and stating that amaas could not be confounded with these varioliform diseases, the provisional conclusion arrived at on the relationship of amaas to small-pox was that the former is small-pox modified by some undetermined factor or factors. It must be remembered that amaas so called by the natives of South Africa has been endemic here for centuries. The word "amaas" means milk, and the pearly appearance of the vesicles gives them the appearance of containing a drop of milk, hence the descriptive term of "milk-pox" given by the natives to the disease. This malady gives the Kaffirs little concern, and beyond a few

days' indisposition they are little the worse for the visitation. Amaas shows predilection for the aboriginal native, and half-castes and Europeans though unvaccinated are very much less susceptible to infection. The protection afforded by vaccination is indubitable, and it was chiefly for this reason that one held that amaas could not be a totally distinct disorder, but was related in some way or other to small-pox. On the other hand, the great mildness of the malady, its freedom from complications and low mortality, mark it, in these respects at any rate, as totally different from the formidable disease small-pox, which one had seen to decimate the unvaccinated, as occurred in Cape Town in 1881, when the Malays for religious scruples refused to be vaccinated. In July, 1911, Dr. Emilio Ribas of Brazil read a paper in London entitled, "Alastrim, amaas, or milk-pox" before the Society of Tropical Medicine and Hygiene. He observed it at Sao Paulo in agricultural labourers from Bahia, which is in direct trade communication with Africa, and concluded that alastrim was a disease *sui generis* and not modified small-pox.—I am, etc.,

Cape Town, June 16th.

W. E. DE KORTÉ.

MEASURES AGAINST TUBERCULOSIS.

SIR,—As one who had the privilege of listening to Professor Calmette's tuberculosis lecture at Edinburgh on June 7th (fully reported in your columns of June 24th, p. 997) may I be allowed to add a word of appreciation and comment? The address may well become historical, and will perhaps be looked on in after-times as having given the official *coup de grâce* to the idea that tuberculosis is in itself a bad thing and that we are to be saved from it. On the contrary, Professor Calmette wants us all to have it, and from an early age, only in not too big or too strong doses, so that we may become accustomed to it gradually. He proposes that in future we should have our tuberculosis administered to us either through the mouth or by inoculation.

It is to be observed that the whole thesis of the eminent French bacteriologist indicated a sane tendency to return to the methods of Nature. Of the large audience of robust savants who followed his lecture it is safe to say that the majority must have had direct personal experience of the tubercle bacillus at some period of their lives, and each and all had obviously come satisfactorily through the ordeal. This immunity, be it noted, these persons had attained naturally—that is, if one may so say, subconsciously, without having attacked the problem directly.

Thus Professor Calmette's demand is that medical science in future should do—exactly what Nature is now doing; only that we should, if possible, control the tendency which Nature occasionally shows towards somewhat slapdash methods.

It is probable that our present large incidence of genuinely pathological tuberculosis is due much more to defective resisting power than either to too strong or too frequent doses of the "poison." Should not the main purpose of public health now be to raise our resisting powers? It is the response of the human organism rather than the circumstances to which it is subjected which seems to be the main element in our modern hygienic problem.

The further questions that now press for solution are, How far is the resisting power by virtue of which the individual satisfactorily tackles his tuberculosis problem a *specific* resisting power? Further, how far are mere laboratory methods in a position to deal with such a problem? I fancy we tend too much in this connexion to overlook the more empirical methods of acquiring pathological knowledge (less intensive but covering a wider field) which are used daily by the general practitioner.—I am, etc.,

Edinburgh, June 21th.

A. J. BROCK.

DENTISTRY IN INDIA.

SIR,—Though there are three hundred and twenty millions of people in India, and though the provision of medical and surgical aid is a matter for which the State makes itself in some degree responsible, there is not in the whole of the British Indian Empire a single institution for the teaching of dentistry. There are in the larger towns a certain number of qualified practitioners, mostly European or Parsi. But the mass of the people if they desire anything more than an extraction have to rely upon the services of men who have served as clerks or mechanics to regular dentists, or may have picked up a few dental hints at random, and conjoined dentistry with a trade, such as watchmaking. For the

average Indian villager it is easier to get his leg amputated or a stone removed than to get a tooth filled.

I am aware that it is generally said that Indians have good teeth. Theirs are probably better than ours, but they could be a great deal better than they are without rendering dental aid superfluous. I have served twenty-five years in India and have looked, and I know.

The political situation has so dominated all considerations in India for many years that defects of the kind I have referred to have received no attention. There is room in India for at least five thousand practitioners of a rank corresponding to that of sub-assistant-surgeon. A dental training institution for each province is greatly to be desired, but a start might be made with one for all India. If Government will not undertake the work the object is one which is not unworthy of private beneficence. Why delay further?—I am, etc.,

June 27th.

AN INDIAN CIVILIAN.

TOBACCO SMOKE AND CANCER.

SIR,—In the article on the "Etiology of Cancer" (JOURNAL, June 17th, p. 964) it is said:

"The comparison of cancer mortality rates upon smokers and non-smokers is also not demonstrative, because the habit of smoking is not distributed at random; . . . the minority of a population in respect of any widespread social custom are likely to differ from the majority in more ways than one."

I shall be glad if the writer of this article will kindly examine for himself the parts of my annual reports on the health of Woolwich in which I have endeavoured to show that cancer of the mouth and throat (not cancer as a whole) is closely connected with smoking. The argument depends on the following contentions:

1. Chronic irritation is an admitted cause of cancer.
2. Smoking causes a chronic irritation of the mouth and throat, by friction, hot air, nicotine, etc. The hot air is probably the chief factor.
3. Whereas 75 per cent. of persons dying of cancer of the mouth and throat were found to have been excessive smokers, only 16 per cent. of persons dying at advanced ages from other causes were large smokers. Persons dying of cancer of other parts only had 22 per cent. of excessive smokers.
4. Women rarely have cancer of the mouth and throat, and few women over 40 smoke.
5. The deaths from cancer of the mouth and throat have increased *pari passu* with the increased consumption of tobacco in the last twenty years.

It is not a question of smokers and a minority of non-smokers; it is a comparison between slight and profane smokers. It is not a question of cancer as a whole, but of cancer of the particular part which smoking irritates.

I must allow that the number of the deaths investigated was not large, and I must admit the difficulty of getting accurate information; but I submit that my figures are sufficient to encourage further inquiry in the same direction, and that if such inquiry confirms the contention that there is a close correlation between smoking and cancer of the mouth and throat such correlation can hardly be brushed aside as of no importance.—I am, etc.,

Buckhurst Hill, June 21st.

SIDNEY DAVIES.

* Dr. Davies seems to mistake our meaning strangely. Why he should suppose that the passage quoted from our article supports the contention that a close correlation between smoking and cancer of the mouth if discovered can "be brushed aside as of no importance" we do not know. Our intention was to emphasize the fact that before we can tell what such a correlation means, "before we can" be sure that there is (in popular language) causation, not correlation, such statistics need a prolonged scrutiny, a scrutiny which is rarely rewarding unless the data are numerous and homogeneous.

THE NATURE AND SIGNIFICANCE OF HEART SYMPTOMS.

SIR,—Dr. P. D. Strachan, in the BRITISH MEDICAL JOURNAL of July 1st wrote:

"In his article of April 15th Sir James Mackenzie perpetuates an error in dynamic terminology which has been universal among English writers . . . and among teachers, ever since my student days. I refer to his use of the terms 'reserve force' and 'rest force,' where 'power,' not 'force,' is what is meant."

In a letter published in the BRITISH MEDICAL JOURNAL of April 22nd, 1911, under the heading "Heart Failure," I made

a like comment on a lecture delivered by Dr. Mackenzie before the Royal College of Physicians. I then said:

"The two new terms 'rest force' and 'work force' are both unfortunate. Dr. Mackenzie says, 'The rest force is the minimal force which the heart can exert to maintain the circulation at a level consistent with life.' Why call a force which the heart exerts a 'rest force'? A force in action may be small, but it is not a 'rest force.' Moreover, 'rest force' and 'work force' are mutually confusing, since they are both working forces. . . . And why use the term 'force' where force is not meant? It is not 'the minimal force which the heart can exert,' but the minimal *energy* which the heart can expend 'to maintain the circulation at a level consistent with life,' with which Dr. Mackenzie is dealing. Better terms therefore would, I think, be 'minimal (or normal or standard) energy' and 'reserve energy.'"

Dr. Strachan's letter shows that my protest of eleven years ago has availed little. I hope his may have better success.—I am, etc.,

Cl'ist St. George, Devon, July 1st.

D. W. SAMWAYS.

THE RECOGNITION OF AORTIC INCOMPETENCE.

SIR,—I have followed with great interest the discussion on the above subject which was initiated by Dr. Brockbank's paper. I must acknowledge to being a little surprised that practically no reference was made to blood pressure measurements, which make a Corrigan's pulse a measurable phenomenon: the difference between the crest of the wave and its lowest point corresponds to a measurable number of millimetres of mercury, which surely bears a direct relation to the amount of regurgitation.

What leads me to write, however, is Professor Rudolf's letter (March 18th) explaining his hypothesis that "in certain weakened states the pulmonary muscular ring is occasionally . . . relaxed . . . and . . . permits of leakage there." I wish to suggest that something similar happens sometimes in auylostomiasis, but at the aortic valve.

Dr. Lyell and I have at present under our care a Chinaman, aged 27, admitted with the regular signs and symptoms of auylostomiasis, including an advanced degree of anaemia. On April 10th, forty-eight hours after admission and before anticholintic treatment had been administered, his systolic pressure was 140 mm. and his diastolic only 40 mm. The apex was beyond the nipple line, and in the sixth space.

After one treatment he returned home, but came back to hospital on April 30th; on May 1st his blood pressure was found to be systolic 110, diastolic 58, and the apex was in the nipple line.

At no time has any diastolic murmur been made out in this particular patient—even with a wooden stethoscope—no matter whether he was lying or standing. In other patients, diagnosed as suffering from aortic incompetence, on admission such a murmur was heard, but after the blood condition had improved the murmur was lost and the "Corrigan" character of the pulse had disappeared, the systolic pressure having dropped 15 to 25 mm. and the diastolic having increased. In two such cases the Wassermann test was found to be negative.

I can conceive of no better explanation of these facts than that the aortic muscular ring was so relaxed as to permit of leakage.

Of course we also got cases of organic aortic incompetence, with positive Wassermann reaction, but they do not differ from similar cases seen in England.—I am, etc.,

Swatow, China, May 9th.

G. DUNCAN WHITE.

THE DIPLOMA IN PUBLIC HEALTH.

SIR,—I have been expecting every week that some D.P.H. better known and qualified to speak than myself would have publicly protested against the recent decision of the General Medical Council regarding the public health diploma, but as there is no indication that the profession seems to interest itself in the subject I crave your indulgence for a short criticism of the situation created by the Council.

It is quite true that the student of the present day has more than enough study imposed on him without increasing his burden, but the necessity for an extended knowledge of hygiene is becoming more apparent every day, and the ignorance of the newly qualified practitioner on the subject is, to say the least of it, disappointing. Why should the General Medical Council discourage the general practitioner from making himself conversant with the rules of public health and helping himself to understand the responsibility about which his duties often call upon him to express an opinion? A distinguished member of the Council declared that the

ordinary practitioner has no need for ornamental qualifications; such cheap sarcasm is unworthy of a gentleman holding such a distinguished position.

To abolish the D.P.H. for general practitioners I consider to be a most retrograde step. Reform is probably necessary; increasing the standard for those who wish to devote themselves to special work, but leaving the general practitioner a chance of expressing a qualified opinion in health matters.

Few young medical men know anything about school, institutional, or dairy hygiene; comparatively few can express an opinion on private water supplies, make a rough analysis of milk, or prepare a diet sheet for an orphan school; and yet these are questions that general practitioners are often consulted about. Again there are not many doctors outside the despised list of D.P.H.s. who can lay their hands on Acts of Parliament respecting health legislation, who can tell if drain pipes are correctly laid, or gauge the full significance of vital statistics. It may of course be contended that these subjects can be studied privately, but if there is not a definite object in view, it is not likely that a man already overworked will sit down to grind at now subjects.

Apart from its utility, the syllabus for the D.P.H. is most fascinating, and a candidate cannot help being interested and surprised at the possibilities it opens out to him. I quite agree that the diploma should not be taken within two years of registration. If the D.P.H. is too elementary for those who intend devoting themselves exclusively to this work a higher degree similar to a fellowship could be instituted which all medical officers of health in towns of over 50,000 should be required to possess. I would also urge that one of the essentials for this higher degree would be that the candidates should produce evidence that they had been engaged for at least two years in general practice.—I am, etc.,

Catford Hill, S.E., July 2nd.

T. E. WHITE.

THE PLIGHT OF THE RUSSIAN PROFESSION.

SIR,—In answer to the appeal on behalf of the Russian medical profession, I have great pleasure in enclosing a donation. As one having worked for several months with Russian medical men in South Russia during 1919, I can testify to the awful conditions that must have overtaken them. Even in 1919 many thousands of doctors were without necessary clothing, and their families in dire distress. Out of the black cloud of revolution one bright star has always shone—namely, the work of the Russian medical and nursing professions. It is not necessary to bring further proof of the sad plight the medical men are in at present in Russia. However, one statement I can make which will afford further proof of the good work done by Russian doctors: when compiling statistics we found that from December, 1918, to August, 1919, the death rate from typhus fever was as follows:

Medical men	40 to 50 per cent.
Nursing sisters	30 per cent.
Patients	8 to 10 per cent.

Surely these figures tell the whole tale of heroic work carried out by the medical and nursing professions in Russia. What of the families of those left from the married doctors included in the 40 to 50 per cent.?

In conclusion, I can testify to the sterling good-heartedness and unflinching cheerfulness of these Russian medical men, and have personally received many kindnesses from their hands.—I am, etc.,

July 1st.

G. K.

SERUM BY THE MOUTH.

SIR,—The practical advantages of the oral administration of vaccines and serums are of sufficient importance to justify the hope that the question raised by Dr. Allison in the *JOURNAL* of July 1st (p. 29) and by the review of *Hormone Therapy* (June 17th, p. 955) will receive further attention at the hands of those who have the opportunity of comparing the oral with the hypodermic method.

At times of epidemics, in the case of children, and in the Services the oral administration of prophylactic vaccines would save much time and trouble, and moreover it is perhaps not sufficiently recognized that many people are deterred from having vaccines by a dislike of the operation of hypodermic injection, simple and safe though it is.

Provided vaccines are not vitiated by the gastric juices there seems no reason why the absorption from the stomach should not be as effective as from under the skin, especially

if some simple routine is adopted such as giving the dose on an empty stomach accompanied by a gastric stimulant.

This letter is written in the hope that more will shortly be heard of this subject with regard to effectiveness and dosages.—I am, etc.,

July 2nd.

R. N.

CAESAREAN SECTION.

SIR,—My attention has been drawn to an article in the *BRITISH MEDICAL JOURNAL*, June 10th, 1922 (p. 911), on Caesarean section by Mr. S. J. Cameron of this city.

I congratulate him on having 79 consecutive sections, with one fatality, in his recent cases. He then proceeds to mention that in his later cases he has changed his abdominal incision to one through the right rectus, that he turns the uterus inside out to remove placenta and membranes, and that the patients are nursed in the Fowler position.

It is a well-known fact in Glasgow that some years ago I introduced these improvements in this operation at the Royal Maternity Hospital, Glasgow. I enclose a reprint from the *Glasgow Medical Journal* of my communication to the Royal Medico-Chirurgical Society of Glasgow, April, 1921, when these improvements were fully discussed, Mr. Cameron being present. An abstract of same appeared in the *BRITISH MEDICAL JOURNAL*, April 30th, 1921 (p. 641).—I am, etc.,

Glasgow, July 1st.

JAMES H. MARTIN, M.D.

Obituary.

FRANCIS W. BAILEY, D.S.O., M.R.C.S., L.R.C.P.,
Anaesthetist, Liverpool Royal Infirmary; Lecturer on Anaesthetics,
University of Liverpool.

WE regret to record the death of Dr. Francis W. Bailey, in his 50th year, after a long and lingering illness, borne with great fortitude. The elder son of the late Dr. Bailey, an esteemed practitioner in Liverpool, Francis W. Bailey was educated at the Liverpool College, studied medicine at University College, Liverpool, and qualified in 1894. After holding residential posts at the Royal Infirmary in the special departments, he devoted his life work to anaesthesia. In this subject he soon became a leading authority, and he contributed papers of practical value on the administration of anaesthetics by various methods to the *BRITISH MEDICAL JOURNAL* and the *Liverpool Medico-Chirurgical Journal*. At the outbreak of the great war he served first as an officer with the 3rd West Lancashire R.F.A. on the western front. For his gallant conduct he was awarded the D.S.O., and in subsequent battles he was twice mentioned in dispatches. He was wounded in the first series of battles of the Somme, and there is no doubt that the fatigue and hardship of the war left his constitution impaired. Previous to the war, in 1910, Dr. Bailey was elected, in the Conservative interest, a city councillor, and, with the exception of a year, held that position up to his death. He was a public-spirited man, and devoted much careful thought in the execution of his duties in the City Council.

Dr. Francis W. Bailey was a man of versatile interests. He was a member of the Historic Society of Lancashire and Cheshire. He took a keen pleasure in archaeology and was well acquainted with the history of his native city and the landmarks of antiquity in the two counties. He was an ardent cyclist, and there were few counties which he, in company with his brother, had not visited a wheel, always devoting their attention to the historical features of the villages and towns they traversed.

His funeral was a military and civic one. As lieutenant-colonel, the rank he held up to the time of his death, full military honours were accorded. The Lord Mayor and other members of the City Council were present to pay their respect to one who had so assiduously fulfilled his civic duties. A great number of medical men, friends, and colleagues attended the service, which was conducted by the Rev. J. R. Beresford, who was with Colonel Bailey on the western front. The chaplain's short address set forth in simple language the high qualities Dr. Francis W. Bailey displayed on the field as a gallant soldier and a devoted medical man. At the graveside the Last Post was sounded, and a little farther away the sounds of the reveillé closed the impressive ceremony. He was a bachelor, and leaves behind a devoted sister and a brother, Dr. Reginald T. Bailey, to cherish the memory of a man who did his life work well and earned the affectionate regard of all who knew him. In demeanour quiet and by nature thoughtful, he seemed to be

UNIVERSITY OF LEEDS.

A CONGREGATION of the University was held in the Town Hall, Leeds, on July 1st, when the following were among the degrees conferred by the Vice-Chancellor:

M.D.—G. Colin H. Nicol.

FINAL M.B., CH.B.—H. P. Fowler, Mary Heller, R. E. Jowett, J. A. Trewick, Frances M. Webb, H. Brostoff, T. S. Davy, G. Denton, S. Erdheim, M. Gordon, Doris M. Langley, H. E. Lapienis, S. Levy, Kathleen M. Peacock, H. Sugate, Margarita Ward, Bertha Wheatley, F. E. Woodroffe.

* With second-class honours.

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—Part II: E. Baron, Frances M. Webb, J. Bernstein, F. Clegg, R. E. Crockett, Dorothy M. Edgecombe, S. Erdheim, M. B. Hare, Mary Hollier, H. E.

idus, E. Linfoot, P. Obermann, M. M. Sutherland, J. A. Walker, Part I: R. Chester, R. Lirnan, R. Marinkovitch,

H. M. Pettit, J. W. Pickard, B. Stross, H. Taylor, W. Thistlethwaite, S. Thompson, D. Yates.

D.P.H.—H. Sims, Marjorie Harris.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—C. W. Ewing, F. A. Kerr, G. C. F. Roe.

Medical News.

DR. ALEXANDER MILLS KENNEDY, who was appointed Professor of Medicine in the Welsh National Medical School last October, has been elected dean of the school, in succession to Professor David Hepburn, C.M.G., who has held the office of dean of the Medical School at Cardiff for a number of years.

DR. DAVID FYFE, of the Middle Temple, was called to the Bar on June 28th.

THE Academy of Sciences of Madrid has presented the triennial prize, founded in 1905 in memory of Echegaray, to Dr. Ramón y Cajal, who has lately retired from his chair in the Medical Faculty of the University of Madrid.

DR. T. CASPAR GILCHRIST, of Baltimore, will deliver the annual oration, on the progress of dermatology, before the London Dermatological Society, at St. John's Hospital, Leicester Square, W.C., on Thursday, July 13th, at 7 p.m.

A PARTY of final-year students from Bristol University recently paid a visit to Bath under the direction of Dr. J. Odery Symes. After a short lecture on the physiological effects of the baths and waters, the party was taken round the bathing establishment, where demonstrations were given.

PLANS for amalgamating all institutions for higher education in the maritime provinces of Canada into a central university at Halifax, Nova Scotia, with the assistance of the Carnegie Foundation for Research, have been announced, and representatives of the different colleges are at present considering the proposal.

THE Greek plays which used to be given by the boys in the open-air theatre, Bradford College, were interrupted by the war: they have been resumed this summer, the play selected being the *Antigone* of Sophocles. The performance, which was most impressive, has been witnessed on four occasions by large audiences.

THE Queen, from whom the Convalescent Auxiliary Hospital at Roehampton takes its name, has been graciously pleased to accept a copy of the book on *Artificial Limbs and Amputation Stumps* by Mr. Muirhead Little, surgeon to the hospital. The Queen of Italy, who likewise takes a great interest in the subject, has also accepted a copy.

A BILL has passed the New Jersey (U.S.A.) Legislature requiring applicants for marriage licences to submit to a medical examination.

A CHAIR of therapeutical hydrology and climatology has been created at the Bordeaux Faculty of Medicine, with Dr. Sellier as its first occupant.

THE Governors of the Manchester Children's Hospital, Pendlebury, have decided to establish a special orthopaedic department, and have appointed Mr. Robert Ollerenshaw, F.R.C.S., to be orthopaedic surgeon to the hospital. Out-patients will be seen at Gartside Street on Friday mornings, and twelve beds will be reserved at Pendlebury for cases needing operative treatment.

THE War Office Committee on Shell Shock, which has been engaged in its inquiry for more than two years under the chairmanship of Lord Southborough, has completed its report; and the hope is that this will be presented to Parliament within a fortnight at latest. The report is voluminous (nearly two hundred pages), and the recommendations are unanimous.

THE thirty-third Congress of the Royal Sanitary Institute, which is to be held at Bournemouth, will be opened by the President, the Right Hon. J. E. B. Seely, M.P., on the afternoon of Monday, July 24th. Some 500 delegates appointed by public health bodies in this country and in the Dominions, and by certain foreign governments, are expected to attend. The work of the Congress will be conducted in sections and by conferences. Full particulars can be obtained from the Secretary of the Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W.1.

DR. J. GARDNER, on the occasion of his leaving Moxborough, has been presented by his friends and patients with a gold watch suitably inscribed, and Mrs. Gardner with a gold wristlet watch.

A COURSE of lectures with instruction on orthopaedics will be given at the Institut Calot, Berek-Plage, Pas-de-Calais, France, from August 7th to August 13th. Particulars can be obtained from Dr. Fouchet at the institute.

PRACTICAL courses in dermatology and the treatment of venereal disease will be given next autumn in connexion with the clinic of the Hôpital Saint-Louis, Paris, under the general direction of Professor Jeanselme. The course in dermatology will begin on October 2nd, and that on venereal disease on November 13th.

DURING the fifth International Neo-Malthusian and Birth Control Conference a session to discuss contraceptive technique, open to the medical profession only, will be held in the Kingsway Hall on Friday, July 14th, from 2.30 to 5 p.m., and on the same morning there will be a discussion on the general medical aspects of birth control. Medical practitioners wishing to become honorary members of the conference should communicate with the medical secretary, Dr. B. Dunlop, 71, Harley Street, W.1. We are informed also that a conference on birth control, called by the Mayor, will be held in the Council Chamber of the Deptford Town Hall on Monday, July 10th, at 8.30 p.m. The M.O.H. for the borough (Dr. C. S. Thomson) will open the discussion.

THE annual meeting of the Poor Law Medical Officers' Association will be held on Thursday, July 13th, at 3.30 p.m., at the offices of the British Medical Association, 429, Strand, W.C. 2. The newly elected President, Sir Arthur Newsbolme, will deliver an address. The council's report, to be presented at the meeting, states that much work on behalf of district medical officers throughout the country has been done during the year and many inquiries dealt with. The council throughout this period has held its meetings on the premises of the British Medical Association, and notes that this has coincided with larger and more profitable attendances. During the absence abroad, for reasons of health, of the honorary secretary, Dr. Withers Green, Dr. John Alcindor has undertaken his work.

THE Royal Society of Medicine recently instituted a new order of Associates open to qualified men and women (whether British or otherwise) who within five years of their first professional qualification apply to the Council of the Society for election. Associates are entitled to attend the ordinary meetings and take part in a discussion in any Section. They have the use of the reading, writing and smoking, conference, and dressing rooms, of microscopes and other facilities for the examination of specimens; they may also be granted the use of the Mares Beck Laboratory. In addition they have all the advantages of the library, except that they may not borrow more than one volume at a time. Associates pay an annual subscription of three guineas, which becomes due on October 1st of each year, but no admission fee. Associateship terminates on the expiration of five years from the date of the associate's first professional qualification, but an associate then elected to the Fellowship is not required to pay an admission fee as such.

AT the Lincolnshire Assizes on June 29th, before Mr. Justice Branson, Dr. Sydney Firth, of Grantham, was charged on four counts with "using a certain instrument with intent to procure the miscarriage of a certain female." The prisoner pleaded not guilty. The prosecution was opened by Mr. Hugo Young, K.C., who said that in four separate cases Dr. Firth saw women who were pregnant, and at their request performed illegal and felonious operations on them with a view to procuring miscarriage. Evidence was taken from women with whom the prisoner had lodged or held rooms for the purposes of his practice, and from the four women who were alleged to have been operated upon. The latter corroborated counsel's statement as to the payment by them of sums of money. Other witnesses having been called for the prosecution, Mr. A. M. Lyons addressed the jury on behalf of Dr. Firth, and criticized the evidence. The jury found the prisoner guilty on all four counts, and he was sentenced to seven years' penal servitude.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CONTRIBUTORS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

INCOME TAX.

"M. S." inquires whether the emoluments received by medical officers of asylums are assessable for income tax.

** The answer is yes, except such emoluments as are receivable in kind, and consequently being inconvertible into money, do not fall within the principle laid down in "Tennant v. Smith."

"W. W." has been refused a deduction of 5 per cent. on gross bookings for bad debts.

** An allowance can be claimed for bad debts estimated to be irrecoverable, but for that allowance it is probably necessary to estimate each debt separately. "W. W." may perhaps know that most practitioners base their returns on gross cash receipts, thus avoiding the necessity of dealing with bad debts which can seldom be even approximately estimated.

"J. A. A. R." inquires whether it is necessary to stamp an envelope directed to the income-tax collector or inspector.

** We understand that where a stamp is not affixed the Post Office collects double the amount of the stamp charge on delivery of the letter, notwithstanding that it is marked "O.H.M.S." and contains nothing but official matters.

SKIN DISEASE POSSIBLY DUE TO ENDOCRINE DEFECT.

A CORRESPONDENT writing from Ireland requests suggestions for treatment in the case of a boy, aged 15 years, who has never previously suffered from any serious illness, but during the last two years has noticed small pustular spots on both ears. He has been treated with tonics containing, among other things, arsenic, and also with local applications, but without effect. During the last twelve months the nails of his fingers and both large toes have become brittle and cracked, with occasional supuration round the matrices. Our correspondent inquires whether this may be a case of calcium deficiency or whether parathyroid is indicated.

** A dermatologist to whom we have referred this problem thinks the condition probably due to deficiency of some internal secretion, and suggests a trial of one of the preparations made from the endocrine glands—for example, hormone or polyglandin. He states that he has been disappointed with the results obtained from the exhibition of parathyroid.

VISION TESTS FOR THE MERCANTILE MARINE.

A. K. R.—The vision tests for candidates for the mercantile marine are detailed in the Regulations relating to the Board of Trade of Masters and Mates in the Mercantile Marine, Majesty's Stationery Office, or any bookseller, 1921. Price 1s. net. It is described as a reprint, with alterations, of the 1918 edition. A general statement of the visual requirements is given on pp. 14–16, detailed information on the manner of taking the tests on pp. 76 and 77. For form vision the apparatus used is based on Snellen's test types, sheets of letters of graded sizes. Paragraph 6 gives the requirements thus: Standing at exactly 16 feet from the test type, which is exposed in an appropriate manner and illumination, the candidate is required "to read correctly at least nine letters in the sixth line and eight letters in the seventh line of a sheet. If the candidate does this he may be considered to have normal vision and passed. The candidate may use either or both eyes at his option. Inquiry shows that the sixth line of this test card is equal to 5.6,7, and the seventh line to 5.5 of Snellen's

test types for use at 5 metres. Such test types are printed and can be obtained at several opticians'. The method of testing the colour vision is also given in detail; the whole of the test is made with a lantern by which coloured lights may be exposed, to be named by the candidate. If he mistakes red for green or green or red, he fails. If he mistakes a white light for red, but after correction makes no further similar mistake, he is passed. If he repeatedly calls red white, or white red, he is referred for further examination.

LETTERS, NOTES, ETC.

IS MUMPS PAROTITIS?

DR. G. WASHINGTON ISAAC (London, W.C.1) writes: On January 12th I saw a lad suffering from swollen submaxillary glands on both sides but with no visible swelling of the parotid, and no pain or tenderness. His throat appeared to be normal. He had come from a public school where there were many cases of mumps. Before I saw him he had been seen by a consulting physician who gave a tentative diagnosis of mumps. Three weeks later his mother was affected in an exactly similar manner. On April 5th I attended a typical case of mumps, and on April 22nd another in the same family. On May 1st I awoke and found I had a hugely swollen neck due to inflamed submaxillary glands. I also had slight fever, which lasted a few days, but no pain in or tenderness of the parotids. Three weeks later my daughter developed typical parotitis.

MECHANICAL MEASURES IN INTESTINAL STASIS.

MR. CORTLANDT MACMAHON, M.A. (Instructor for Speech Defects and Breathing Exercises at St. Bartholomew's Hospital), writes: By the courtesy of a member I was present when Sir Arbuthnot Lane spoke on May 30th, at the Royal Society of Medicine, on intestinal stasis. Sir Arbuthnot inquired what was suggested outside surgical aid to clear up the condition in severe cases. With the greatest deference I suggest that prophylactic treatment of a mechanical type would often prevent the possibility of the condition arising. I also suggest that many cases of intestinal stasis will yield to the same treatment. The origin of the condition is, I believe, either a constitutional or, more likely, an acquired weakness of the abdominal wall, for which there may be many causes. This soon develops visceroptosis, of which intestinal stasis is a constituent element. Medical treatment gives great relief; massage may relieve temporarily; paraffin and a belt no doubt in some cases do good, but in all these a feature is missing, and that is, the splaced organs is not given. In ill show, in addition to the giving-way of the abdominal wall, a marked falling-in of the lower ribs, which is a natural and inevitable consequence of prolapse of the great organs under the diaphragm; there is, therefore, no longer adequate room for the organs in the abdominal cavity. For recovery this accommodation must be re-established and, by daily exercises carried out quite easily in a recumbent position, the lower ribs are made to expand so that they are almost in a vertical line with the axilla, and in time this condition becomes permanent. When this occurs there is ample room for the organs once more. The abdominal muscles are trained to have an extraordinary power of contraction, so much so that the abdominal wall can be retracted almost to the spinal column. Further exercises, all in a recumbent position, are carried out by the operator with practically no exertion to the patient; the function normally.

... or the patient can day is given to the Sir Arbuthnot Lane spoke of the terrible depression of these patients, amounting to almost a suicidal tendency. In the treatment set out above an improvement in the mental condition occurs in a few days. I suppose many children with the pot-belly condition are candidates for intestinal stasis, unless the abnormality can be controlled. I write as a layman only—with, however, some considerable experience of the physical treatment of visceroptosis patients sent to me by the kindness of the medical profession.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 27, 30, 31, and 32 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 28 and 29.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 20.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£ s. d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

MEDICINE.

25. Leukaemia and Severe Anaemia in Childhood.

J. L. MORSE (*Boston Med. and Surg. Journ.*, May 18th, 1922) publishes a study of 37 cases. No cases in infancy, nor of haemophilia, purpura, and secondary anaemias due to haemorrhage or to sepsis, have been included. Morse states that myelogenous leukaemia is very rare in children, but he records one fatal case in a boy of 4 who died suddenly. The liver and spleen were enormously enlarged and showed no typical changes. There were 12 cases (4 boys and 8 girls), the ages ranging from 2 to 13 years. The duration of disease in 11 cases was from three to thirteen weeks, in one case apparently nine months. In one the blood was normal prior to scarlet fever, and in another the disease occurred after a fall. No possible causes were discovered in the other cases. The symptoms varied, but haemorrhages occurred in all but one case. Anaemia, enlargement of lymph nodes, abdominal pain, vomiting, weakness, fever, and anorexia were common. An enormous increase of white cells, chiefly mononuclears, even up to 1,000,000, was found in every case. There were 18 cases of severe anaemia with moderate or low leucocyte counts, but with a high percentage of mononuclears. In one there was a doubtful history of malaria, but no plasmodia were found, and in another an alveolar abscess, but no improvement followed extraction. The cervical glands were enlarged in 15 cases. Vomiting, weakness, and haemorrhages occurred frequently as in the other series. The spleen was enlarged in 12 cases, and the liver in 16 cases. The Wassermann test (2 cases) and tuberculin test (6 cases) were negative. The haemoglobin was below 50 per cent. in 15 cases; leucocytes below 30,000 in all but 2 cases—in the majority of cases they were entirely or chiefly of lymphocyte type, but in 3 cases large mononuclears predominated. Blood platelets were seen in only 8 cases; normoblasts in 4 cases. One of these had many megakaryoblasts. Morse discusses the question whether this group should be termed "lymphatic leukaemia in an aleukaemic stage" or a form of severe anaemia. He thinks the condition is due to functional failure of bone-marrow. In a girl of 5 and a boy of 8 there was great enlargement of liver and spleen; the girl had a number of normoblasts and myelocytes, lymphocytes 69 per cent., but polymorphs much diminished. In the other case polynuclear neutrophils (86 per cent.) predominated. Haemoglobin was reduced to 35 per cent. and 25 per cent. A boy aged 8½ years died after three years' illness. The liver was just palpable, and pigmentation of the skin resembled Addison's disease. Haemoglobin 15 per cent.; many megakaryoblasts; red cells 860,000; white 8,000; small mononuclears 61 per cent. A girl aged 9½ years died after sixteen months' illness. Her skin was dirty yellow, with deeper pigmentation of axillae, groins, and nipples. At 8½ years she had severe epistaxis. The liver and spleen could not be felt. Haemoglobin 25 per cent.; in other respects the blood picture was almost identical with the preceding case. In both cases the Wassermann and tuberculin tests were negative. The author regards both these as cases of severe aplastic anaemia, though the coagulation-time in the latter suggests the possibility of purpura. Transfusion was done several times in this case, and there was temporary improvement. In the case of a boy who died at 9½ years the illness lasted twenty months; it commenced with epistaxis and headache, and occasional purpuric spots. Haemorrhages ceased after six months, but haemoglobin = 20 per cent.; red corpuscles 736,000, white 5,700; small mononuclears = 90 per cent.; one normoblast; very slight anisocytosis or poikilocytosis. There was no enlargement of liver, spleen, nor of lymph nodes. He improved somewhat and showed no sign of tuberculosis, etc., but peripheral lymph nodes began to enlarge. He developed acute otitis media and mastoiditis, which were cured by operation. Six months before death the haemoglobin = 25 per cent.; the blood picture was otherwise almost unchanged. This was apparently a case of severe aplastic anaemia, not due to infection, as its progress was unchanged by the otitis media. The last case had a similar blood picture to the above. A boy, aged 2½ years, had otorrhoea for five to six months, and became very pale and weak. There was general slight enlargement of liver, spleen, and lymph nodes, and a foul discharge from the right ear. Haemoglobin 25 per cent.; red corpuscles 1,272,000, white 6,600; normoblasts 6 per cent., megakaryoblasts 3 per cent., polymorphs 42 per cent. only. After tonsillectomy he improved, and lymph nodes, liver, and

spleen all diminished. The otorrhoea persisted. Four months later he returned with severe purpura—gums oozing; liver, spleen, etc., enlarged. Haemoglobin 43 per cent.; white cells 29,000; mononuclears 85 per cent. He was transfused; but bleeding did not cease for a month. His otorrhoea persisted; a retropharyngeal abscess ruptured and drained into the throat; many other abscesses were opened and drained. He recovered, and at 9 years of age appears quite well. This case suggests that infection or intoxication may be the source of these severe anaemias, though undiscovered in the other cases.

26. Gastropostosis and the Shape of the Thorax.

FABER (*Ugeskrift for Læger*, May 11th, 1922) finds that the frequency of gastropostosis increases considerably with the degree of deformity and narrowing of the chest. The position of the stomach, as shown by the x rays after a "contrast" meal, and when the patient stands up, may be such that (1) it is entirely above the umbilicus; (2) the lesser curvature is above, the greater below the umbilicus; (3) the lesser curvature is 2 cm. or less below the umbilicus; or (4) it is at least 2 cm. below the umbilicus. The author has devised what he calls the "epigastric index." A line is drawn from the umbilicus to the lower end of the sternum. At the middle point on this line a horizontal line is drawn from one costal arch to the other. The epigastric index is obtained by multiplying the length of this horizontal line by 100 and dividing by the length of the vertical line. The author finds that the average epigastric index is 59.3 for men and 45.4 for nulliparous women. A high index was usually associated with a high position of the stomach among men and nulliparous women. But in parous women there was little relation between the epigastric index and the degree of gastropostosis, which was evidently determined chiefly by child-bearing. One of the author's patients was a tall, thin woman with an epigastric index of 30 and the lesser curvature of the stomach several centimetres below the umbilicus. After six years, during which her weight rose from 46 to 80 kg., the lesser curvature was 8 cm. and the greater curvature 3 cm. above the umbilicus.

27. Syphilis in Country Practice.

LEREDDE (*Paris méd.*, March 4th, 1922) remarks that though numerous practitioners state that they have never met with syphilis in the country, it is really very frequent there in its nervous, visceral, and osteo-articular manifestations, although examples of chancre or secondary lesions are rarely seen. He quotes Dr. Etienne de Vernon (Eure), who in the course of sixteen months among 524 patients found 243 cases of undoubted syphilis, consisting of 82 of acquired syphilis and 161 of the inherited disease. Among the 82 cases of acquired syphilis there was only one instance of a chancre, 2 of secondary syphilis, 12 of tertiary cutaneous lesions, 27 of nervous syphilis (including hemiplegia, paraplegia, general paralysis, epilepsy, and tabes), 3 of cardiac or aortic syphilis, 1 of pulmonary syphilis, 1 of anaemia, 1 of exophthalmic goitre, and 1 of chronic rheumatism. In 22 cases maternal syphilis was discovered. In addition to 243 cases of undoubted syphilis were 19 cases of probable or possible acquired syphilis and 117 of probable or possible inherited syphilis. Leredde points out that syphilis is one of the principal causes of mortality at all ages. It is estimated that it is responsible for 80,000 deaths annually in France, and this figure might possibly be raised to 150,000 if all the consequences of syphilis were included; according to Couvelaire half the deaths among infants within the first three days after birth, including stillbirths, are due to syphilis, or 19,000 deaths a year. Leredde recommends the institution of antisyphilitic dispensaries throughout France with laboratories attached.

28. Serum Treatment of Dysentery.

LANTIN (*Philippine Journ. of Science*, December, 1921) administered antidyentery serum to cases of Shiga and Flexner dysentery by five different methods—namely, per rectum alone, intramuscular injection and per rectum, intramuscular injection alone, intramuscular and intravenous injection, and intravenous injection alone. In administering the serum per rectum the patient assumed the knee-chest position and was first given a cleansing enema of sodium bicarbonate (1.5 per cent.), followed by another enema of 60 to 100 c.cm. of starch solution with 15 drops of laudanum so as to diminish the irritability of the intestines; half an hour later 30 to 80 c.cm. of antidyentery serum was given through a long rubber tube. The nine cases treated in this

way by daily serum enemata all recovered, but the treatment was not adopted for serious cases, and even in the milder cases some were unable to retain the serum long. The intramuscular injections were given into the buttock, the dose being 20 c.cm. every four hours for the first three days and 20 c.cm. twice a day thereafter. In the intravenous injections 10 to 20 c.cm. was found to be the best dose, and 1 c.cm. was injected four to six hours previously so as to avoid anaphylaxis. Since the cases selected for the different methods of administering the serum varied considerably in their severity, it is not possible merely by considering case mortality to appraise the value of the different routes of injection, but there were clinical grounds for believing that the rectal injection of the serum resulted in alleviation of the symptoms as shown by diminished pain and tenesmus, decrease in number of stools, and fall in temperature. The serum is known to have both bactericidal and antitoxic powers, therefore this, the simplest method, should be used in patients well enough to retain the enemata. The combined method (serum per rectum and intramuscular injection) gave as good results as any, and is regarded as the safest method. Intravenous injection produces immediate effects, and in severe cases is clearly indicated, but it should be used with caution because of the greater danger of anaphylaxis and emboli.

29. The Actual Caution in the Treatment of Paralysis from Vertebral Disease.

WIRTH (*Klinische Wochenschrift*, April 8th, 1922) records his experience of the use of the actual cautery in paralysis from vertebral disease. He supports the view of Quincke as to its value, and thinks it may be of service, especially in spastic paraplegia following tuberculous disease of the spine. He records three successful cases. Examination of the first case revealed disease of the fourth and fifth dorsal vertebrae; diminished sensation from the fifth dorsal segment downwards; spastic condition of the legs; Babinski reflexes; ankle-clonus. After open-air treatment for tuberculosis the bone symptoms disappeared, but the spastic paralysis increased, so that the patient could not stand. The spine was cauterized. Prompt improvement occurred and he was soon able to walk. Two months later the spasm of the legs had disappeared, and there was no ankle-clonus, no Babinski reflex, and no sensory disturbance. In the second case there was disease of the twelfth dorsal and first lumbar vertebrae. The chief symptoms were pains in the thighs, formation in the feet, ataxic gait and ataxia of the left leg. The spine was cauterized. The ataxia, pains, and paraesthesia disappeared rapidly. In the third case (myelitis of the lumbar region and conus—chiefly in the anterior grey matter) the chief symptoms were priapism, marked atrophy of the left leg and slight of the right. After cauterization of the spine the priapism soon disappeared, the movements of the left leg improved, and the atrophy was less marked. The cautery is applied on each side of a vertebral spine during slight ether narcosis.

30. The Suprarenals in Asthma.

HURST (*New York Med. Journ.*, March 11th, 1922) considers that asthma is due to an inborn condition in which the broncho-motor part of the vagus nucleus is abnormally active, and consequently responds too readily to blood-borne irritants and to peripheral and psychical stimuli. The overactivity of the broncho-constrictor fibres of the vagus are kept in check by the activity of broncho-dilator fibres of the sympathetic owing to the constant secretion of adrenalin. Hypersensitiveness to certain proteins largely depends upon their depressing effect upon the suprarenals manifesting itself in depression of their normal activities in connexion with the blood vessels, alimentary canal, or bronchi, giving rise in different individuals to vasomotor disturbances—for example, urticaria, vomiting and diarrhoea, or an attack of asthma. Fright may stop an attack of asthma through its stimulation of the sympathetic and suprarenal secretion, and that asphyxia may have the same effect explains the relief which an asthmatic experiences if he continues walking up to a moderate degree of dyspnoea, and for this reason exercise should be encouraged if there is shortness of breath during the first quarter of an hour. An adrenalin injection cuts short an acute attack of asthma more rapidly than any other treatment, 1 minim of 1 in 1,000 adrenalin chloride solution being sufficient, since it is not necessary to produce such general symptoms as a rise in blood pressure or rapid pulse. The injection should be given at the beginning of an attack and before it has fully developed, and in such small doses no unpleasant immediate or after effects result. It is the only form of injection which is justifiable for self-administration, because of the necessity for its being given directly the first symptoms of an attack are experienced.

SURGERY.

31. Indications for Splenectomy in Children.

THE conditions for which relief or cure by splenectomy may be indicated are present in the first years of life more frequently than is generally accepted. BARTLETT (*Amer. Journ. Dis. of Children*, April, 1922) has collected reports of fifty-one cases of splenectomies in children under 14 years of age. He states that haemolytic jaundice, Banti's disease, Gaucher's disease, and Von Jaksch's anaemia are conditions for which relief or cure by splenectomy may be the only treatment. It is desirable to remove the spleen in the early stages of the pathological process for which splenectomy is indicated. Of those conditions to which splenectomy appertains, haemolytic jaundice, familial or acquired, offers the greatest hope of a cure by removal of the spleen. In Banti's or Gaucher's disease the decision to remove the spleen is based on the presence of a large spleen, persistence of secondary anaemia after repeated blood transfusions, and a physical disability which makes the individual a chronic invalid. Splenectomy for these conditions may give relief of symptoms and serve to prolong life. Von Jaksch's disease is probably not an independent condition. Cases of haemolytic jaundice have the advantage of the distinguishing sign of icterus. With regard to leukaemia, this disease, above all others, must be excluded in a decision to remove the spleen; removal of the spleen is contraindicated. The writer reports three cases in which splenectomy was carried out. In one case of Banti's disease radium treatment proved of no avail, and he considers it of little use for this condition. With regard to blood transfusion, if a child with an enlarged spleen and a secondary anaemia fails to improve after two or more transfusions, splenectomy is advisable.

32. Syphilis of the Epididymis.

FRASER (*British Journ. of Derm. and Syph.*, June, 1922) points out that there are two forms of syphilitic implication of the epididymis—interstitial epididymitis and gummatous formation, the former of which may be acute or chronic. In acute interstitial epididymitis pain is sudden in onset and accompanied by a dragging sensation in the scrotum and along the vas; there is great tenderness and swelling, which invariably commences in the globus major and very soon involves the body and tail; the epididymis becomes uneven and nodular, probably due to infiltration with lymphocytes and plasma cells and hyperplasia of the fixed elements. Chronic interstitial epididymitis may follow an acute attack, but more frequently is slow, painless, and insidious in its onset and occurs in a much later stage of the disease. Here also the globus major is first affected, and irregular, diffuse, nodular infiltrations make their appearance. The patient's attention is directed to the condition often only because of the gradual increase in the size and weight of the scrotum due to the accompanying hydrocele. The author reports an unusual case of bilateral syphilitic interstitial epididymitis which occurred eighteen years after the initial infection and was acute on one side and chronic on the other. There was unilateral implication of the vas, but the prostate and seminal vesicles were not affected and both testes were normal. There was no other evidence of syphilis, and the condition responded rapidly to treatment. A previous gonococcal infection may have acted as a predisposing factor in determining the site for the syphilitic activity.

33. Indications for Removal of the Spleen.

MORAWITZ (*Klinische Wochenschrift*, April 15th, 1922) briefly describes the haemolytic and other functions of the spleen and gives an interesting summary of the indications for removal of that organ, viewed from the standpoint of the physician. Apart from surgical conditions, removal of the spleen is indicated in diseases in which abnormal haemolysis occurs in the spleen and through the spleen. This is most clearly the case in chronic haemolytic (or acholuric) jaundice. The symptoms are usually completely obviated by this operation, but the author advises it only in the severe forms of the disease. In pernicious anaemia and leucoerythraemia the operation is dangerous and the results are unfavourable. In polycythaemia the operation is useless, but x-ray treatment is now successfully carried out. Recently successful results have followed removal of the spleen in the rare cases of true morbus maculosus (purpura) or essential thrombopenia (Frank), but caution is necessary in the diagnosis, as thrombopenia, with haemorrhagic diathesis, occurs as a symptom in a number of varied diseases. The operation is only advisable when the previous history and clinical examination show that the case is one of the essential and chronic forms of this affection. In Banti's disease permanently successful results may be obtained by removal of the spleen in the first and second stages of the disease. In many other forms of splenic enlargement the exact diagnosis is often

difficult and the indications as to operation are less clear. In hypertrophic cirrhosis of the liver (Hanot's form) the spleen has often been removed, but though improvement has followed permanent results have not been obtained. In Gaucher's form of splenomegaly removal of the spleen has only been followed by temporary results.

32. Diagnosis and Treatment of Tuberculosis of the Mastoid.

STRANDBERG of the Finsen Institute in Copenhagen (*Hospitalstidende*, March 15th, 1922) notes that, by the inoculation of guinea-pigs, it can be shown that 10 per cent. of all cases of mastoiditis are tuberculous. The differential diagnosis is of great importance to treatment, which, when the disease is tuberculous, should be by Finsen light. Of thirteen cases thus treated after operation, all but one terminated in recovery, and in the one exception the patient discontinued the treatment prematurely. The author agrees with Eeggaard in his finding that in 63 per cent. of all cases of tuberculous middle-ear disease and mastoiditis the onset of the disease is associated with severe pain and high fever, and it is impossible to exclude tuberculosis because the onset of the disease is not painless and is associated with a rise of temperature. The macroscopic appearance at the time of operation is of no value to the differential diagnosis, which rests solely with the guinea-pig.

33. Tracheo-cutaneous Suture in the Treatment of Foreign Bodies.

COLLET (*Lyon Médical*, April 25th, 1922) records a case of partial asphyxia in an infant due to swallowing a plum stone which lodged in the right bronchus. The trachea was opened and the two sides sewn to the skin; by pulling the sides apart a good view could be obtained and local cocaine anesthesia easily managed. The author has treated several cases of foreign bodies in the air passages in this way, where for various reasons bronchoscopy was either impossible or unsuitable. He says it is simpler and more effective than putting in a tube, which often prevents the foreign body from escaping. The method is most applicable in the case of smooth, rounded, voluminous foreign bodies.

34. Ocular Symptoms of Epidemic Encephalitis.

FOSTER (*Amer. Journ. Ophthalmol.*, January, 1922) records observations upon the ocular symptoms in two cases of epidemic encephalitis, and urges the desirability of carefully reporting such observations in order that, by clinical grouping of the symptoms in individual cases, greater assistance may be given to early diagnosis. In the first, a man aged 46, there was partial loss of function of the left abducens and, to a less degree, of the left levator palpebrae, with total loss of function, sudden in onset, of both inferior recti. The following day the patient slept almost continuously, and the paresis of the ocular muscles became more marked, the left eye having almost no movement except inward, while in the right eye the externus was the only muscle which seemed to function normally. The pupils were small, and reacted quickly to light but not to accommodation. After five days of lethargy recovery slowly began, and three days later the ptosis had almost disappeared, and the other extrinsic muscles, with the exception of the left externus, had regained their functions. In the second case, a man aged 44, the striking feature was the very fleeting nature of all the ocular symptoms. Commencing with ptosis of the left upper lid and paresis of the left superior and inferior recti, and followed by complete paralysis of the left internus, at the end of six days the ptosis was less and all the ocular paralysis had disappeared. After an uninterrupted convalescence the patient was discharged apparently well, but later developed fits of drowsiness preceded by ptosis, partial or total, until he sank into complete lethargy with the eyes fixed straight forward, and the left cornea was much more sensitive than the right. The pupils in the first attack reacted both to light and to accommodation, but there was little reaction to light later.

35. Primary Cold Abscess of the Tongue.

ACCORDING TO TADDEI, director of the Surgical Clinic at Pisa University (*Il Policlinico*, Sez. Prat., March 27th, 1922), primary tuberculous abscess of the tongue is generally regarded in the textbooks as very rare. Although it is certainly not a frequent occurrence, he has seen four examples of the condition, in three of which he removed the tuberculous lesion. Three were in women and one in a man. As a rule the abscess is situated deeply in or between the muscles of the tongue, but in some cases it is localized in the submucous tissue. The course of the disease is fairly rapid; regional adenitis is rare and occurs late. The diagnosis is made by animal inoculation. The prognosis is favourable provided that a complete extirpation of the focus is carried out.

OBSTETRICS AND GYNAECOLOGY.

36. Maternal Mortality in New Zealand.

ACCORDING TO H. JELLYETT (*New Zealand Med. Journ.*, April, 1922, p. 35), the general maternal mortality in New Zealand is somewhat excessive. For 1920 the mortality for the whole country was one in 154 births, and in the districts with the highest mortalities 89 deaths occurred among 6,876 births—a proportion of one in 77. About three-quarters of the deaths were certified under one of the four headings: sepsis, eclampsia, post-partum haemorrhage, placenta praevia. The mortalities from all of these causes were considerably higher than those shown in the statistics of the Rotunda Hospital during twenty-six years; the basis of comparison is said to be approximately fair, for although hospitals enjoy special advantages in treatment the average morbidity of the cases on admission is greater than in ordinary practice. The high death rate from eclampsia is attributed in part to too frequent treatment by Caesarean section. The unusually large distances separating the residences of doctor and patient account, in part at any rate, for the high mortality from placenta praevia and post-partum haemorrhage. Deaths from sepsis numbered one in 459 births; it is suggested that the chief contributory causes are increased virulence and prevalence of septic organisms, operative midwifery, and unsuitable surroundings. Unnecessary operative midwifery consists in prophylactic ante- or post-partum douching, unnecessary vaginal examinations, unnecessary forceps applications, and interference with the third stage of labour. With regard to it is probable that a private house of a hospital, but inadequately or improperly equipped or staffed, is the most dangerous place for delivery. For too excessive maternal mortality the remedies suggested are: (1) Alterations in the relations between the medical attendant and the patient in cases of normal labour; as suggested by Fairbairn (this JOURNAL, March 19th, 1921), the duty of the doctor in the future will consist chiefly in the supervision and "vetting" of pregnant women, the detection of abnormalities, and the treatment of complications—in other words, to secure a normal labour or to treat an abnormal one. The doctor whose time is not wasted in attending normal labour will be free from the temptation to interfere, for the purpose of saving time, by application of forceps or hasty expression of the placenta. (2) Improvement of obstetrical homes and erection of midwifery blocks for paying patients in connection with the large general hospitals. (3) Improvement of obstetrical education as regards the amount of practical teaching and the opportunities of practical experience by students. (4) It should be recognized that obstetrical and gynaecological specialists are essential in large centres of population, and that it is impossible for them to become efficient unless there are places made for them on hospital staffs and unless they get the support of practitioners.

37. Induction of Labour by the Use of Castor Oil and Quinine.

FOR induction of labour A. C. WILLIAMSON (*Surg., Gynec., and Obstet.*, June, 1922, p. 812) gives 1½ oz. of castor oil at midnight in primiparae and about 7 in the morning in multiparae. A hot enema is administered as soon as the oil is effective, and quinine sulphate is given in four half-hourly doses of 5 grains. If the attempt fails, a second trial is not made until ten days later. Administration of quinine is stopped if the patient complains of nausea or ringing in the ears. Of 300 cases, of which about one-half were primiparous, this procedure was followed by onset of labour in 46.6 per cent. Labour should be carefully watched; there were twenty cases of fulminating labour, and occasionally tetanic uterine contractions led to foetal or maternal distress. It is admitted that in the successful cases the patient had arrived at or passed term as fixed by dates; the head was fixed or beginning to engage in the pelvis; the cervix was partially or completely obliterated and the internal os would admit a finger; and the uterus showed irritability by readily contracting as a result of manipulation. In the therapeutic mechanism two factors are concerned—a direct action of quinine on the uterine muscle, and stimulation of sympathetic centres as a result of increased intestinal peristalsis due to the castor oil.

38. Capillary Circulation in Pregnancy Nephropathies.

NEVERMANN (*Zentralbl. f. Gynak.*, April 22nd, 1922) recapitulates his findings, confirmed by other observers, that in cases of eclampsia, of the pre-eclamptic condition, or of "pregnancy kidney," alterations in the cutaneous capillaries may be observed with the capillary microscope, and consist in lengthening of the capillaries, thickening of the venous to a greater extent than of the arterial radicles, and retardation

of the intracapillary blood flow, which becomes tortuous and shows periodically partial or complete stases. He believes that the severity of these alterations in capillary circulation afford a measure of that of the existing toxæmia; retardation and stases are most marked in association with eclamptic convulsions, and become less manifest as improvement is found clinically to occur. After recovery the passage of blood through the capillaries quickly becomes normal, but alteration of capillary form may persist for some weeks. Similar alterations of capillary circulation occur in cases of nephritis in non-pregnant subjects and of mitral disease, arteriosclerosis, and vascular neuroses. The benefit following venesection in pre-eclamptic and eclamptic conditions is explained, partially at least, by the observation that an amelioration of capillary circulation may be demonstrated to ensue. Nevermann has found retardation of capillary flow and periodic stases in capillary microscopic examinations of the capillary circulation in twisted ovarian tumours at laparotomy. That other capillaries than those of the skin show similar circulatory variations he has proved by observing the cutaneous capillaries as well as those of the mesentery, the ileum, and the uterus, both in animals and in patients after opening of the abdomen. In a patient on whom Caesarean section was performed for eclampsia he was able to demonstrate in the uterine capillaries morbid changes corresponding closely with those seen in the skin capillaries. The inference that in pre-eclamptic and eclamptic conditions impairment of capillary circulation takes place not only in the skin but in the viscera and brain is of importance in connexion with the etiology of eclampsia.

41. Signs of Intrauterine Death.

ACCORDING TO A. B. SPALDING (*Surg., Gynec., and Obstet.*, June, 1922, p. 754), crepitation in the foetal head bones, which it is sometimes possible to elicit by vaginal or abdominal palpation, constitutes practically the only positive diagnostic sign hitherto reported of intrauterine death of the foetus. The patient may or may not complain of malaise, vomiting, breast changes, or vaginal discharge of blood or clear fluid. The medical attendant may or may not note changes in the blood pressure, a slight increase of temperature, a subnormal temperature in the cervix uteri, or stationary or diminished height of the fundus. As a sign pathognomonic of intrauterine death the writer describes the finding by x-ray examination of marked overlapping of the skull bones with distinct signs of shrinkage of the skull contents. The latter finding distinguishes the overlapping of the bones from that associated with compression of the foetal head during labour.

PATHOLOGY.

42. Etiology of Malignant Disease and Leukaemia.

YOUNG (*Edin. Med. Journ.*, June, 1922) has isolated a micro-organism with specific characters from thirty-four out of forty malignant tumours examined and from four carcinomatous growths in the mouse. The tumour tissue was incubated under partially anaerobic conditions in a fluid medium rendered acid by the fresh addition of a solution of 0.2 per cent. HCl placed in the medium so as to surround the tumour fragment. The parasitic form of this organism consists of a minute phase which is passed in the nucleus of the cancer cell, the presence of this irritant supplying constant stimulus to growth and accounting for the riotous proliferation which characterizes malignant disease. In culture this organism is found to be markedly pleomorphic, and granules, bacillary, coccoid, and filamentous forms are described. Two strains have been identified—the human and the mouse type—resembling each other in their morphology and general cultural characters, but differing in the ease with which they can be isolated. The results of the injection of these cultures into mice are not yet complete, but as far as they go they demonstrate that inoculation induces lesions which are either toxic or proliferative in type, though only two out of a large number of inoculated mice have developed carcinomatous tumours. In many cases, however, a marked degree of lymphoid proliferation occurred, leading to a condition similar to lymphoma or lymphoid sarcoma. In three cases of human leukaemia an organism similar to that described for human carcinoma has been recovered from the blood, and cultures of this organism when injected into mice produced lesions similar to those found with mice infected with the mouse strain. The author concludes that malignant disease and related leukaemia phenomena, both in the human subject and in the mouse, are dependent upon an infection of the body-cells by an organism which has specific characters.

43. The Action of Certain Fats on Oseous Metabolism.

MOURIQUAND and MICHEL (*C. R. Soc. Biologie*, May 27th, 1922) set out to study the action of certain fats in their relation to the antiscorbutic factor. Guinea pigs fed on barley, hay, and a fatty substance—either butter, olive oil, or cod-liver oil—all succumbed with typical scurvy. A second series of animals was then given a mixture of barley, 10 c.cm. of lemon juice, and either 5 grams of butter, or 2.5 c.cm. of olive oil, or 2.5 c.cm. of cod-liver oil. Out of seven guinea-pigs fed on the dietary containing butter, only one died of scurvy; out of six fed with olive oil not one developed scurvy; while all the ten animals fed on cod-liver oil died between the 29th and 107th days with definite scorbutic lesions of the bones. Not only was this last group affected with scurvy, but skin troubles were present, the coats of the animals being coarse and bristling. In order to study further the effect of cod-liver oil, this substance was added to a diet which was already complete—namely, one consisting of barley, hay, and lemon juice. The animals of this series remained well, displaying neither osseous nor cutaneous lesions. These results with cod-liver oil are very surprising and unexpected. They must, of course, be considered merely as applying to the guinea-pig, but they do suggest that there may be certain foods which exert an adjuvant or a retarding effect on the development of scurvy. They likewise provide a warning not to regard all fat-soluble factors as necessarily similar in action.

44. The Incidence of Syphilis in the Dead-house.

L. MELCHIOR (*Hospitaltidende*, May 12th, 1922, p. 106) has investigated the frequency with which syphilis can be demonstrated clinically and by post-mortem evidence among hospital patients. Between 1914 and 1920, 5,865 bodies were examined at the Communal Hospital in Copenhagen, and in 4,717 cases the ages of persons dying over the age of 15 years were recorded. Among these there were 358 (7.6 per cent.) with anamnestic, clinical, or post-mortem evidence of syphilis. The percentage proportion of men to women was 69 to 31. There was a considerable difference in the age at death of these syphilitics and of all the hospital cases. Thus, 65.4 per cent. of the syphilitic died between the ages of 30 and 60, whereas only 46 per cent. of all the patients died between these ages. Only 25.1 per cent. of the syphilitic died after the age of 60, and only 7.2 per cent. after the age of 70; whereas the corresponding percentages for all the patients were 44 and 22.5 respectively. A definite history of infection was obtained only in 54 per cent., and the date at which infection had occurred was given in barely 50 per cent. In this category, about every other patient had died from five to twenty-five years after infection, and 15 per cent. within the first three years of infection. But only in 7 out of 26 of these cases could the cause of death be traced to syphilis. Syphilitic changes were found post mortem in 248 cases—that is, in 69.3 per cent.—the percentage rising with the age of the patient, being only 23.5 among persons dying under the age of 30, and 83.5 among persons dying after the age of 70.

45. Serological Test for Cancer.

THOMAS and BINETTI (*Les Néoplasmes*, No. 2, March, 1922) claim to have devised a serological test for cancer based upon the reducing power of the serum. The ingredients necessary for the test are: (a) an extract of a malignant tumour prepared by maceration of the tissues in 1 per cent. sulphuric acid and a mixture of alcohol and ether, the two solutions after evaporation being redissolved in distilled water, neutralized and sterilized; (b) a 1 in 320 solution of methylene blue containing 1 c.cm. of glycerine; (c) normal serum and serum to be tested. On mixing graded quantities of normal serum with the extract and one drop of the methylene blue solution, reduction of the methylene blue gradually takes place, beginning at the bottom of the tube. This reduction does not take place for at least sixty minutes when normal serum and extract are mixed with methylene blue; but if the serum comes from a case of cancer the reduction often commences within ten minutes and is complete much earlier. In 63 patients not suffering from malignant disease negative results were found, while 80 cases of cancer affecting different organs all gave a positive result. But in an advanced case of inoperable cancer the blood reaction was negative, a result which the authors ascribe to a failure of the defensive ferments due to the advanced stage of the disease. Again, it would appear that an individual whose parents have suffered from cancer may show a positive reaction although not suffering from a tumour at the time, this being an indication, we are told, of a predisposition to malignant disease. Cases are recorded in which the reaction was positive before the removal of the tumour and negative afterwards.

This is how you can sell your car while you are using it —

REGISTER particulars with the Motor Sales Registry, stating the approximate price you would accept when you wish to sell. You will then be advised from time to time of prospective purchasers at *your* price. This information you are free to act upon or ignore, according to whether you wish to sell your car or not at the time.

We make it our business to find purchasers of good second-hand cars, a service we can render you all the year round. NOVOCAIN

Original make
COCAINE-FREE Local Anæsthetic.

Price per Tube of 10 Tablets, 1/6; per post 1/8. Literature and full technique on request.

THE SACCHARIN CORPORATION, Limited.

(Pharmaceutical Dept.)

36, 37, Queen Street, London, E.C.4.

MINOR SURGICAL OPERATIONS IN GENERAL PRACTICE.

Small operations which the General Practitioner is daily called upon to perform, including Suture, Incision, excision, painful manipulation of wounds and fractures, amputations, etc., can be harmlessly and painlessly accomplished in the Surgery or Consulting-room by the injection of 1 to 1 per cent. Novocain Solution, made by dissolving one "A" tablet in Physiological Saline Solution.

Six to seven times less toxic than Cocaine

OVERFATNESS

Dr. WILLIAM T. CATHELL'S TREATMENT.

Reliable and Harmless.

Doctors are frequently asked by their patients for something to make them thinner, and Dr. WILLIAM T. CATHELL'S method shows how this may be done safely and gradually.

A verbatim copy of a Lecture, by William T. Cathell, A.M., M.D. Baltimore, on Overfatness, will be sent free on application to

ALFRED BISHOP, Ltd., Manufacturing Chemists, **48, SPELMAN STREET, LONDON, E. 1.**

Proved by Doctors

Whether for town or country work there is no medium powered car the equal in value of the 12/14 h.p. De Dion Bouton.

Its ease of control, ample power, splendid acceleration, silky suspension and economical running (30-35 miles per gallon) make it particularly suitable for medical men's work.

When fitted with our new All-weather Curtains the car can be transformed quickly into an enclosed carriage as illustrated.

The Curtains open and close with the doors and when not in use are carried at back of front seat.

Chassis with Tyres ... £495
Complete Cars from £610 to £825

A British Medical Association Lecture ON SOME ASPECTS OF CARDIAC DISEASE.*

BY
JOHN HAY, D.L., M.D., F.R.C.P.,
HONORARY PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL.

So much of what appears in the journals dealing with the neo-cardiology, as it has been termed (a term applied partly, I think, in derision), is so technical and so difficult of comprehension that there is a tendency to miss those points which are of real and genuine practical value.

When one remembers that Mackenzie's book, *The Study of the Pulse*, was published in 1902, and that it is only ten years since the electrocardiograph began to be applied seriously to the elucidation of the arrhythmias, it is not difficult to understand why there is still so much haziness and even frank ignorance concerning the newer and more correct views of cardiac disorders. During the last twenty years the whole conception of the arrhythmias and their relation to cardiac failure has been changed.

If these views were nothing more than a revised nomenclature with little or no bearing on prognosis and treatment I would not trouble to discuss them with you; but the reverse is the case. Recent work has made diagnosis more certain, and correct knowledge of the heart is more concise, and as a natural corollary prognosis and treatment are placed on a surer and sounder basis.

I propose to discuss one form of arrhythmia, an irregular action which is extremely common, and which for this, if no other reason, is of considerable importance to us all as practitioners. I refer to auricular fibrillation, and may I make one point here—it is this: irregular action of the heart is not merely a matter of degree—there are definite, clearly demarcated types, varying fundamentally, and it is most important to be able to differentiate between those forms of irregular action which are of no moment and those which indicate serious changes.

Auricular fibrillation is not only of common occurrence, but it is also a serious handicap to the efficiency of any heart, healthy or diseased. The term "fibrillation" is unfortunately often applied rather loosely, showing a lack of appreciation of the fact that fibrillation is a sharply defined condition. An auricle is either fibrillating or it is not fibrillating, and the presence of fibrillation can generally be recognized during the ordinary clinical examination without any special instruments other than a stethoscope and a trained intelligence. At least 50 per cent. of all cases of persistent irregularity are due to fibrillation, and 60 to 70 per cent. of the patients admitted into hospital suffering from cardiac failure show this form of arrhythmia. Experimental work by Eyster and Swartbout on dogs has shown that fibrillation diminished the cardiac output by 40 per cent., and from clinical evidence it is clear that the inception of fibrillation means a sudden and definite increase in the load which the heart has to bear.

Before describing in detail the characteristics of this change and the method of its recognition may I first present a few clinical pictures?

In each of the five patients to be described the heart was beating in a frequent and disorderly manner—possibly with great frequency. It is well to remember that fibrillation may be associated with all grades of cardiac distress.

CASE I.

I have in my mind a man of 69, subject to attacks of "palpitation and fluttering action of the heart." These would come on at any time and without apparent cause, and last as a rule several hours. Their onset was sudden—he knew the moment they began and he knew also the moment of their cessation. He was not greatly distressed by them, but during an attack he did not feel quite himself and was conscious of the rapid and irregular action of his heart. Otherwise he was not inconvenienced and had no hesitation, for example, in setting out on a journey by train. (See Fig. 6.)

CASE II.

The second patient, a man of 80, was entirely, or almost entirely, unconscious of any change in his heart. On cross-examination, however, he admitted that he was more easily puffed, and that on effort he experienced a little palpitation; beyond that, nothing. The heart showed no deviation from the normal except the typical irregularity and slight increase in frequency. (See Fig. 4.)

CASE III.

In the third case the subjective symptoms were more definite. He was apparently a healthy man of 50. On May 19th he ran hard for a train—a distance of three-quarters of a mile. He caught it, but the shortness of breath and the palpitation caused by the extra effort did not pass off as he had expected. They persisted, and when I saw him on May 22nd he still complained of these symptoms and also of a peculiar "dithery and shaky feeling." On examining the heart I found the ventricular rate 140, many of the systoles failing to lend a pulse to the wrist. There were no bruits and no increase in the cardiac dullness. Fibrillation had supervened in a heart which, up to that moment, had been for all practical purposes a sound heart with an ample reserve. (See Fig. 3.)

CASE IV.

The fourth example is that of a woman who had been under observation for years, suffering from mitral stenosis. Up to the present breakdown she has had, in spite of her valvular disease, good cardiac reserve, and has lived a useful and active life within her frankly recognized limitations. She will tell you that suddenly, during the day and the hour, she became conscious of an irregular and rapid action—or she may describe it as a peculiar fluttering behind the breast bone. With this there were some precordial pain and a sense of shortness of breath. These symptoms increased and, as she was not treated, were followed by cyanosis, venous engorgement, and oedema, with distension of the abdomen and some abdominal pain, and an engorged and pulsating liver—all the signs of grave cardiac failure. On examination the action of the heart is found to be extremely rapid; the heart has become dilated, the typical presystolic murmur has disappeared, and the pulse is running, feeble, and irregular.

CASE V.

The last and fifth case is of a different type, but again one with which we are all only too familiar. I refer to the sudden onset of acute and overwhelming cardiac failure in a patient of middle age or of more advanced years. Such a man of, say, 60, in apparently good health, known to have a high blood pressure, awakes in the small hours in acute physical and mental distress. This is characterized by extreme dyspnoea and restlessness; his face is grey and pallid, he is bedewed with cold sweat, and his extremities are cold and clammy. There is no oedema and no engorgement of the liver. The heart is found to be beating tumultuously with extreme rapidity—the "delirium cordis" of the older writers. The radial pulse is irregular in force and frequency, and there are many small and almost imperceptible pulsations, in striking contrast to the apparently forceful action of the ventricles. He dies in a few hours of rapidly progressive cardiac failure chiefly affecting the left ventricle.

These instances are given as illustrations of the varied character of the clinical picture which may be presented by patients in whom auricular fibrillation has supervened. I hardly need to emphasize the fact that in each of these patients it was essential for correct treatment and prognosis that the nature of the sudden change in the heart should be clearly recognized.

What are the characteristics by which it can be recognized? They are largely embodied in the five cases related above.

Onset.—The onset is sudden. The transition from a normal rhythm to fibrillation is instantaneous and patients can often give a clear account of the commencement of the attack. Similarly in those patients in whom the fibrillation occurs in paroxysms the offset may be equally perceptible. On the other hand, fibrillation may not cause any sensations, pleasant or otherwise, until the reserve power of the heart is definitely encroached upon.

Irregularity.—The ventricular action is completely irregular and often frequent when the heart is free from the action of drugs; but the rate may vary within very wide limits, and when moderate the irregularity may not be very noticeable, though if the pulse be observed over a few minutes it is probable that the typical disorderly rhythm will manifest itself, and this will be more noticeable after exercise. It is also not unusual to find that the rate of the ventricular contraction is greater than the pulse rate, since some of the beats fail to be transmitted to the wrist.

Liability to Cardiac Failure.—It is the rapid and relatively inefficient action of the ventricles which increases the liability to cardiac failure, and if preceding the onset of fibrillation the myocardium is unsound, or if there is marked arterial hypertension, the onset of cardiac failure may be rapid and the distress great. It was this type of rapid and irregular ventricular action that was named "delirium cordis" by such writers as Balfour in his delightful book *The Senile Heart*.

Dilatation of the Heart.—When present dilatation supervenes as the result of the rapid and disorderly action and not as the cause, and if the fibrillation ceases the dilatation rapidly disappears. Similarly the heart shrinks when the

* Delivered before the Mid-Cheshire Division, June 15th, 1922.

entriular action is slowed by digitalis, even if the fibrillation persists.

These, then, are briefly the clinical characteristics.

ETIOLOGY.

The etiology is simple. There are two large groups in which most of the cases may be included:

1. *The rheumatic*—in which the most common form of valvular disease is mitral stenosis, and the age period covers from 20 to 50.

2. *The senile*—in which males predominate. In this must be included patients suffering from myocardial degeneration, arterio-sclerosis, and chronic interstitial nephritis.

The remaining cases are those in which the fibrillation originates in infections such as pneumonia and influenza, or results from sudden physical strain.

A point I should like to emphasize here is that fibrillation is not confined to any one type of cardiac lesion. It may develop in any heart, though it is unusual to find it in the absence of some definite pathological condition.

The essential nature of auricular fibrillation is a specific and fundamental change in the activity of the auricles. Normally the auricles contract in response to a stimulus which originates at the sino-auricular node, and this contraction is a co-ordinated movement eventuating in the expulsion of the auricular contents. This ceases when fibrillation begins. The fibrillating auricle thus remains in a state of continued diastole and on inspection its wall is seen to be tremulous. It is not inactive, but its activity is no longer normal.

I do not propose to discuss the cause for this peculiar condition, but the explanation which is at present generally accepted is that of "circus movement," ably described by Sir Thomas Lewis in his Oliver-Sharpey lectures for 1921.

Essential Character of Fibrillation.

Whatever theory of fibrillation is accepted there is at all events no doubt that all evidence of presystolic contraction of the auricle disappears. With fibrillation, for example, the typical presystolic bruit of mitral stenosis is no longer heard—a mitral diastolic may and often does persist, but even when it is audible up to the first sound it has lost its presystolic crescendo accentuation, and in a lengthened diastolic pause the bruit generally fades away before the subsequent first sound.

An analysis of the jugular records taken from the vein shows that the wave a in the phlebogram, so characteristic

FIG. 1.—The jugular pulse is auricular in type; the wave a is well marked and occurs regularly. The murmurs are indicated on the tracing: presystolic, systolic, and early diastolic.

FIG. 2.—From same patient as Fig. 1 after the onset of fibrillation, showing an entire change in the character of both jugular and radial pulses. The rhythm is now disorderly. The wave a present in the previous tracing has disappeared. The murmurs are charted on the record. Note that the presystolic murmur has disappeared.

of systole of the right auricle, is no longer present. On the other hand, there may be, during diastole, peculiar small oscillations in the phlebogram.

Again, the electrocardiograph gives conclusive evidence of the cessation of normal activity in the auricle by the disappearance of the deflection P—a deflection due to auricular contraction and present in every normal record.

At the same time there are in the electrocardiograph numerous small deflections, f f, occurring at the rate of 450 to 500, which are caused by the peculiar electrical changes accompanying fibrillation, and are characteristic of the change.

FIG. 3.—Records showing result of quinidine sulphate from auricular fibrillation. Top record shows irregular action of the ventricles, and the characteristic small deflections f due to the fibrillation. Lower record shows a normal rhythm after 0.4 gram of quinidine sulphate. The oscillations f f have disappeared. A premature beat arising in the auricle is shown at Px.

We have therefore this peculiar condition present in the auricles, and from this fibrillating mass impulses pour upon the ventricles through the normal channel—the auriculo-ventricular bundle. The ventricles respond as best they can

FIG. 4.—Simultaneous tracings of the jugular and radial pulses. Note the absence in the jugular tracing of any wave a preceding ventricular systole. From Case 11. Typical disorderly rhythm.

to this irregular bombardment. The junctional tissues do, however, put some check on the number of stimuli passing through them, and the ventricular rate probably depends on the degree of block present. When this is marked the ventricular rate is infrequent, but when the impulses pass on to the ventricles with little hindrance the rate tends to become excessive. By judicious medication this can be controlled.

FIG. 5.—Typical radial tracings from case of auricular fibrillation, showing lack of correspondence between the length of diastole and the magnitude of the succeeding systole.

Whether the rate be frequent or the reverse the ventricular action is no longer regular—it is disorderly, a haphazard rabble of beats. Exercise increases both the cardiac frequency and coincidentally the degree of the arrhythmia.

DIAGNOSIS.

The diagnosis of this condition during the ordinary clinical examination depends, therefore, upon a clear recognition of these essential characteristics which I have described. Careful cross-examination may elicit valuable information concerning the onset. The change in the character of the murmurs in the case of a patient suffering from mitral stenosis would of course be more than suggestive. But the most significant feature is the specific character of the arrhythmia, and in most instances palpation of the pulse should justify a positive diagnosis. The beats come hap-

hazard; the normal relation between the size of the beats and the antecedent pause no longer holds, and the rate of the pulse is no sure indication of that of the ventricles. The faster the heart the more obvious is the disordered character of the action. When the rate is within normal limits the arrhythmia is more subtle and is less arresting. Even then, however, sooner or later, with patience, the characteristic inconsequence of beats will appear, and suspicion passes into certainty.

Auricular fibrillation presents one other characteristic of great diagnostic value, and that is the specific response to the digitalis group—namely, a marked slowing of the ventricular rate, which is sometimes accompanied by the appearance of "coupled beats."

With these clinical characteristics clearly in mind it should be possible to arrive at a diagnosis, but there are certain forms of irregular action which may cause some little difficulty.

Sinus Arrhythmia.

Each respiratory movement may be associated with a decided arrhythmia, a quickening of the rate with inspiration and a lagging with expiration. When this is unduly exaggerated it may simulate fibrillation, but on holding the breath the heart becomes regular. A clear relationship to the respiratory phases is decisive. This form of irregularity is frequently present in adolescence and is of no moment.

FIG. 7.—This record shows the coupled beat which often occurs when digitalis is pushed in cases of fibrillation of the auricle. It is an indication to stop the administration of digitalis. The second systole in each coupling is ectopic, and is just perceptible in the radial tracing.

Then, if ectopic or premature beats become numerous the arrhythmia simulates that of fibrillation. When occurring only occasionally or at regular intervals, giving rise to a premature or ineffectual beat every second, third, or fourth beat, it is obvious that there is a fundamental or dominant rhythm. Exercise, by increasing the rate, generally brings about a disappearance of this irregularity.

It is this form of arrhythmia which is that most likely to cause difficulty, and there is no doubt that when it is still further complicated by the appearance of "pulsus alternans" it may be impossible to make a confident diagnosis without a

FIG. 8.—Polygraph record showing sinus arrhythmia. The rate is quickened with inspiration and slowed during expiration. *a* = wave due to systole of the auricle, *c* = record of carotid pulse.

polygraph or electrocardiograph record. Similarly cases of auricular flutter and cases of heart-block simulating fibrillation will probably require the employment of instruments of precision before a positive diagnosis can be made; but here again exercise and an increase of the ventricular rate tend to give a regular action.

TREATMENT.

When fibrillation is present the primary object of treatment is to reduce the ventricular contractions to a number

within normal limits. In the most urgent cases of all, when the condition of the patient is so grave that it is obvious that unless the heart is slowed down at once death within a few hours is inevitable, strophanthin must then be administered intravenously in a dose varying from 0.5 to 1 mg. The result is sometimes as satisfactory as it is dramatic. Within an

hour the condition of the patient is altered from one of acute distress to relative comfort: a liver obviously engorged and pulsating has shrunk materially; the cardiac thrust has moved in towards the nipple; the breathing is easier and the heart rate has fallen to a normal frequency.

In less urgent cases full dosage with the tincture of digitalis will probably be inadequate:

5j or 5jss of the tincture as an initial dose, preceded by a purge, will generally give some relief within twenty-four hours; or the tincture may be prescribed in *mxx* doses three or four times in the twenty-four hours.

The digitalis group acts mainly by depressing the junctional tissues and hindering the passage of stimuli from the auricle to the ventricle. Digitalis should be continued until a specific response has been obtained; when the ventricular rate is down to 70 or 80 then the dose must be reduced until just sufficient is taken to maintain this speed. The most satisfactory response undoubtedly occurs in the rheumatic group. The danger is that the patient may cease to take digitalis when the symptoms have disappeared, or as it often happens, the doctor in charge discontinues the administration for fear of the so-called cumulative effects. The result is that within

FIG. 9.—Premature beats.

a few weeks the ventricular rate mounts and the dyspnoea and other indications of cardiac distress return. Certain patients are dependent on the help to be obtained from digitalis, and must never entirely cease to take it in appropriate doses, for digitalis is essential to their well-being.

FIG. 10.—Shows the rapid drop in the heart rate after the injection of the strophanthin, from 120 to 80 in twenty-five minutes.

There are, of course, well-recognized indications for diminishing or stopping digitalis, such as: (1) a ventricular rate of 70 or under; (2) nausea or vomiting or diarrhoea; (3) a "coupled beat" which has appeared as the result of treatment with digitalis. This coupling is a specific response; it is an indication of saturation and that digitalis should be

stopped. The nausea and vomiting may be a true indication of toxic dosage or merely the outcome of the resentment of an engorged stomach to a nauseous drug. If there is reason to believe that the latter is the case, then the digitalis should be continued, but given well diluted or in a bland bismuth draught. When the tincture is badly tolerated the patient can sometimes take with comfort either Nativelle's digitalin granules or the tincture of strophanthus.

In the mildest cases of all, with only a moderate acceleration of the ventricular rate and no distress, regulation of the life and the exhibition of mild haematinics over a long period yield the best result. There are few better cardiac tonics than an adequate supply of good blood to the heart through the coronaries. This is especially applicable to the cases of fibrillation occurring in patients with high blood pressure and arterio-sclerosis.

Can we Stop Fibrillation?

Sometimes fibrillation ceases spontaneously and may never recur; more often it is permanent. Recently much has been written about the action of quinidine sulphate and its power of terminating fibrillation, and it may be of interest to you to refer to this line of treatment.

My experience covers 17 cases in which I have given quinidine with the object of restoring a normal rhythm. In 6 of the 17 the treatment failed. Either the patient could not tolerate the drug or the cardiac failure was accentuated by the quinidine. In 11 of the 17 a normal rhythm was obtained, but two of these relapsed and persisted in their fibrillation. Ultimately in 9 of the 17 patients the normal rhythm was maintained. (See Fig. 3.) It is possible if not probable that as time goes on some of these 9 may fall from grace. On resumption of the normal rhythm some patients feel materially improved, others do not admit to much, if any, benefit.

In my opinion the treatment is not free from danger, and the action of the quinidine should be most carefully checked. My practice is to have an electrocardiogram taken twice a day and the changes in the auricular and ventricular contractions noted. I give the drug in capsules in doses of 0.2 gram spread over the twenty-four hours, so that the patient receives ten doses, or 2 grams, a day. Its indiscriminate use is dangerous, and it should only be given in carefully chosen cases and with the patient under continuous observation. I should like to emphasize this as I have met several instances where, through ignorance, quinidine sulphate has been prescribed recklessly and without any attempt at adequate supervision.

Summary.

Irregular action of the heart is not merely a matter of degree. The types differ fundamentally and their significance varies widely.

The most important group is that of fibrillation of the auricle, characterized by a specific and fundamental change in the activity of the auricles, and a frequent and disorderly action of the ventricles. This increases the load of the heart and is the most common cause of cardiac failure. The recognition of this form of irregularity is not difficult, requiring only the fingers and a trained intelligence.

Fibrillation is not confined to any one particular form of cardiac lesion, but may occur at any age, and when once established tends to persist.

The digitalis group produces a remarkable slowing of the ventricular rate with consequent improvement in the patient.

Auricular fibrillation can in 50 per cent. of the cases be terminated by quinidine sulphate, but in many patients the fibrillation recurs, and the exhibition of this drug is not without danger.

THE Dutch Society for Combating Alcoholism will hold a Congress at the Hague on September 11th, when the following subjects will be discussed: Alcoholism and criminality, introduced by Professor Bongers, and treatment of chronic alcoholism, by Dr. F. S. Meijers.

ACCORDING to a warning issued by the U.S. Public Health Service, leprosy is on the increase in the United States. Statistics show that there are 1,200 lepers at large in twenty-five States, contact with whom may further spread the disease. It also appears to be prevalent in Latin America, for Dr. R. F. Parra, physician-in-chief of the Agua de Dios Leprosarium, Colombia, reports that there are now 2,726 lepers segregated there. Chaulmoogra oil is being used in the treatment of 122 of these patients.

An Address

ON

ACUTE ARSENICAL POISONING.*

BY

SIR WILLIAM HENRY WILLCOX, K.C.I.E., C.B., C.M.G.,
M.D., F.R.C.P.,

PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON, AND LECTURER ON
FORENSIC MEDICINE IN THE MEDICAL SCHOOL.

During the last few years our knowledge of the physiological, therapeutical, and toxicological effects of arsenic has been greatly extended, owing largely to the greatly increased use of preparations of arsenic in the treatment of disease. Thus the use of arsenobenzol derivatives for the treatment of syphilis is worldwide, and many other organic arsenical compounds are largely used in pharmacology. In some cases toxicological effects have followed the therapeutic use of these powerful remedies, and a study of these effects has not only enlarged our conceptions of the physiological and toxicological action of arsenic generally, but it has also stimulated the study of the quantitative tests for the efficiency of important organs of the body—for example, the liver.

Application of advances in pathological and chemical technique has enabled the toxicological effects of arsenic to be studied with more precision and detail, and thus has led to an extension of knowledge.

It will be my endeavour to call attention to the recent advances in our knowledge of the toxicology of acute arsenical poisoning, to give a summary of the salient points, and to illustrate them where possible by classical examples. Acute poisoning by white arsenic and similar inorganic compounds will be considered, and reference will be made to poisoning by arsenobenzol derivatives. Arseniuretted hydrogen will not be dealt with.

Arsenic is one of the commonest and oldest known poisons. It is stated to have been discovered in the third century. Its toxicology overshadows that of all other poisons in importance. Its poisonous properties are known to everyone and its preparations are easily accessible. It is almost tasteless, and can be introduced into food without fear of detection. It produces symptoms which closely simulate natural diseases, and it is not therefore surprising that as a homicidal poison it has easily held the first place for centuries.

Arsenical poisoning may be homicidal, suicidal, accidental, or produced when taken for the purpose of causing abortion or as a quack medicine. Out of 1,000 recorded cases from 1752 to 1911 collected by Witthaus the reasons for taking the poison were as follows:

Homicidal...	42.6 per cent.
Suicidal	23.0
Accidental	20.0
As an abortifacient	3.3
Due to quack medicine	0.4
Motive unknown	10.7

These figures, however, cannot express the true proportions, since suicidal and accidental cases are commonly not recorded. Homicidal poisoning must represent only a small minority of all acute arsenical cases. It is certain, however, that as a poison used for homicidal purposes the absolute number of cases far exceeds those of any other poison.

Preparations Used.

Arsenious oxide (As_2O_3) is the preparation most commonly used for criminal purposes; it is a white inodorous powder, almost tasteless, and slightly soluble in water; about 1/2 grain dissolves in an ounce of cold water, and 6 to 12 grains in a similar quantity of boiling water. It can be added to food and drink without fear of detection, and persons wishing to use it for criminal purposes appear to have no difficulty in obtaining it.

When sold to the public the regulations of the Poisons Acts should be complied with, and one of the conditions of sale of white arsenic is that it should be coloured by the admixture of at least one-sixteenth of its weight of soot or indigo. The evidence of recent notable trials shows that this rule is sometimes honoured in the breach rather than in the observance (Armstrong case).

An easily available source of white arsenic which is often forgotten is the chemical laboratory. The poison can be

* Given before the Medico-Legal Society, July 4th.

obtained in any quantity from wholesale firms for laboratory purposes without any restriction as regards its sale. Every chemical laboratory possesses large quantities of arsenic easily accessible to anyone visiting or using it.

Arsenious oxide is sold in combination with sodium hydrate or carbamate as weed killer. This may be a strong solution of sodium arsenite containing 14 to 40 per cent. of arsenious oxide. The liquid preparation is usually coloured by the addition of aniline dye such as fluoresceine, though during the war it was sold uncoloured. The solid form of weed killer consists of a fine powder usually coloured and containing a high percentage of arsenic. An example of this is Eureka weed killer, which was mentioned in the Greenwood case. A sample was found by Mr. J. Webster to contain 60 per cent. of arsenious acid and to be coloured with phenolphthalein. The powder was very soluble in water and formed a pinkish-red solution which was decolorized by acids.

These preparations are most poisonous; not only may they give rise to accidental poisoning but there is reason to believe that they have been used for criminal purposes on many occasions. An instance of several cases of accidental poisoning due to liquid weed killer occurred in Sussex in 1919, when a sack of sugar absorbed a quantity of liquid weed killer from a leaky tin placed beside it during transit in a railway carriage. The consumption of the contaminated sugar gave rise to acute arsenical poisoning.

In the case *Rex v. Bingham*, 1911, three fatal cases of arsenical poisoning were the subject of inquiry; these were undoubtedly due to weed killer.

In May, 1921, an inquest was held on a woman named Hanktelow at Beckenham, whose death was found to be due to acute arsenical poisoning. In this case the source of the arsenic appeared to be Eureka weed killer.

Liquid preparations known as "wood preservatives," similar in composition to weed killer, are used for destroying insects infesting wood. Since these are not coloured there is great risk of accidental poisoning from their use. The liquid may accidentally contaminate food or drink and give rise to acute arsenical poisoning. An instance has recently been brought to my notice where, after treatment of the interior of a large hut with arsenical wood preservative, the dust of the hut was found to contain a considerable percentage of arsenic, and the air of the interior was also contaminated with arsenic. Arsenic in combination with alkali is used largely in the manufacture of sheep dips, and these preparations have sometimes given rise to acute arsenical poisoning.

A solution of lead arsenate is commonly employed in fruit spraying, and cases of severe arsenical poisoning due to these preparations have been under my care.

There is no doubt that the common use of these commercial preparations of arsenic is a frequent cause of fatal arsenical poisoning, and the time appears to have come when the mode of sale of these preparations should be carefully considered with a view to the safeguarding of the public against risk of accidental poisoning and to prevent dangerous homicidal poisons being so easily accessible to persons with criminal intentions.

Other preparations of arsenic such as sodium arsenite, metallic arsenic, arsenic acid and sodium arsenate, copper arsenite (Scheele's green), a mixture of copper arsenite and copper acetate (Schweinfurth green, Paris green, emerald green), arsenious sulphide (orpiment or King's yellow), have given rise to acute poisoning, usually of an accidental or suicidal nature; and the medicinal preparations of arsenic must not be forgotten as causes of acute poisoning when taken in excessive doses.

SYMPTOMS OF ACUTE POISONING BY ARSENIC.

Arsenic is usually described as an irritant poison. It certainly is an irritant, but it does not kill by virtue of its irritant properties on the gastro-intestinal tract. Arsenic is a most powerful tissue poison, and it is to the toxic effect on the important organs of the body, especially the heart, kidneys, and liver, that a fatal result is due.

The importance of the toxic action of arsenic is too often lost sight of in the medico-legal inquiries concerning cases of acute arsenical poisoning, and attention is too much concentrated on the irritant effects of the poison. It is often assumed that the irritant symptoms of vomiting and diarrhoea are the chief cause of death owing to their exhausting effect on the body, whereas it is the toxic action of the poison on the heart and other organs which is usually responsible for the fatal issue. The vomiting and diarrhoea *per se* are rarely of

themselves the cause of death, and indeed these symptoms can be controlled by medicinal treatment.

In his evidence in the Madeline Smith case, in 1857, that great toxicologist Dr. Robert Christison said, on being cross-examined as regards the large quantity of arsenic present in the stomach of the deceased: "The very fact of poison being found in the stomach at all in the case of arsenic shows that more has been administered than is necessary, as it is not what is found in the stomach that causes death but what disappears from the stomach." In other words, Dr. Christison considered that it was the toxic effect of the absorbed arsenic on the important organs of the body which caused death, not the local irritant effect on the stomach and intestines.

The symptoms of acute arsenical poisoning are very variable in their occurrence, and no hard and fast rule can be laid down as to precisely what symptoms will occur and the order of their occurrence. Thus the same toxic dose of arsenic may in one person produce vomiting first and diarrhoea afterwards, but in another person the reverse may obtain. An example of this has recently come to my notice. Then again some symptoms, such as burning in the throat, thirst, or cramp in the legs, may be prominent in some cases but entirely absent in others.

Criminal cases of arsenical poisoning commonly present symptoms which are due to a succession of doses, possibly each sublethal but poisonous. In such cases the symptoms of acute arsenical poisoning, such as would occur from one single dose of arsenic, may be masked by the appearance of symptoms due to the prolonged action of arsenic—that is, to those of subacute or chronic poisoning. Thus symptoms of arsenical neuritis, or of renal or liver disease, may be superimposed upon those of the acute gastro-intestinal symptoms.

When a single poisonous dose of arsenic is taken by the mouth (one or two grains or over) the interval before the appearance of symptoms is variable. Possibly some peculiar taste of a slightly metallic nature may be noticed, but this is frequently absent. Nausea will probably be the first symptom, and this may occur within a few minutes of taking the poison. The onset of symptoms is dependent on the state of the stomach at the time of taking the poison. If empty there will be little if any delay in the appearance of the symptoms. Much depends also on whether the arsenic is in solution or in the solid state; in the latter condition the onset of symptoms will be delayed. Then again, if the arsenic is in the solid form there will be more delay if the solid is insoluble than if it is soluble.

If the stomach contains food the onset of symptoms will be delayed and also if the poison is taken with food, or if food is taken within a few minutes of the poison. Examples of the variable occurrence of gastric symptoms are shown by the recent Armstrong case, where after a possible poisonous dose there was a delay of one and a half hours before the occurrence of nausea, and of three and three-quarter hours before the occurrence of vomiting, and of eight and a half to ten and a half hours before the occurrence of diarrhoea. In this case (Mr. Martin) the poison was no doubt taken in the solid form (arsenious oxide) with tea and scones and bread-and-butter. In a recent very interesting case published by Dr. St. George (BRITISH MEDICAL JOURNAL, February 5th, 1921) a patient at 8 p.m. took about 180 grains of white arsenic in mistake for magnesia; the poison was mixed with hot milk, and half an hour later porridge and milk were taken for supper. It was not until four hours after taking the poison (12 midnight) that vomiting occurred, and this was accompanied by burning pain in the epigastrium and diarrhoea. At 4 a.m. cardiac failure was shown by coldness, feeble thready pulse, and general collapse; cramps in the legs also occurred. Under medicinal treatment the vomiting and diarrhoea were controlled. At 10 a.m. suppression of urine occurred. The patient recovered from the immediate acute symptoms, but a severe multiple neuritis developed, and the patient died from this three and a half months later. This case is a good example of the action of arsenic, which is that of a protoplasmic poison, the irritant effects not being of themselves fatal.

A remarkable example was mentioned by Dr. Christison in his evidence in the Madeline Smith case, in which a girl took a large dose of arsenic at 11 a.m.; though showing signs of uneasiness, she made a pretty good dinner at 2 p.m. Death occurred in thirteen or fourteen hours after administration. This was a French case and very unusual.

A scientific worker in a factory where large quantities of arsenic were used, and where it was impossible to avoid the inhalation and swallowing of a certain amount of arsenic,

told me that sometimes at night, when the exposure to poison during the day had been great, he suffered from vomiting and diarrhoea—that is, there had been a delay of many hours before the onset of the symptoms.

When a poisonous dose is taken in solution on an empty stomach nausea is likely to occur within a few minutes, vomiting within an hour, and diarrhoea within a few hours. A burning pain in the epigastrium is a fairly constant early symptom associated with the nausea and vomiting. A burning pain in the throat has been described as a symptom. This is usually not marked in arsenical poisoning, and then is only caused by the congestion of the pharynx and oesophagus consequent on the vomiting. In a recent case (Black) burning of the throat was a prominent early symptom, occurring apparently before the vomiting and diarrhoea. Arsenic is not a corrosive poison, and no direct local effects are produced on the pharynx or oesophagus, so that it is difficult to explain an immediate burning sensation except by reflex action.

The vomit will at first contain food and mucus, and may later be darkened in colour owing to the exudation of blood from the gastric mucous membrane; afterwards it may be yellowish and slimy owing to the presence of bile and mucus. The diarrhoea may be severe and accompanied by a good deal of abdominal pain and tenderness. The pain is often of a colicky nature and followed by profuse evacuation. The stools are watery, and may contain minute particles of mucus and blood. In suspected cases the vomit and stools should always be carefully reserved for analysis. The tongue is furred in the early stages, and later may have a silvery appearance, the papillae showing through the fur.

In cases of continued doses, as in the Armstrong case, sordes may appear on the lips, as in a typhoid patient. Cramps in the legs are likely to occur when there is severe diarrhoea; where vomiting and diarrhoea are continuous, thirst may become marked owing to the draining from the body of fluid, the eyes sunken, and the face pinched. The appearance of the patient may resemble that seen in cholera, and the examination of the stools, both chemically and bacteriologically, may be necessary to establish the diagnosis.

Cardiac Symptoms.

A weak and rapid pulse is one of the early and most constant symptoms; it was a marked feature in the Black case and also in the Armstrong case (both Mr. Martin and Mrs. Armstrong). The tachycardia is accompanied by weakness, faintness, and a feeling of collapse. There is no doubt that arsenic has a direct toxic action on the cardiac muscle, and this effect is no doubt the cause of the early death in acute cases.

Hepatic Symptoms.

Arsenic is a direct liver poison, and a microscopical examination of the liver in fatal cases of acute arsenical poisoning shows very marked fatty degeneration. Dr. Spilsbury demonstrated this recently in the case of Mrs. Armstrong. One of the most important functions of the liver appears to be that of the protection of the body from circulating poisons. It is the first line of defence, and when the poison is taken by the mouth it is readily to be understood that since after absorption by the portal vein the poison first passes through the liver this organ receives the brunt of the attack and often is irreparably damaged in consequence. The effect on the liver is a degeneration of the cells and in consequence swelling, so that the bile capillaries become pressed upon and slight jaundice may occur. Jaundice is not a common symptom of acute poisoning by arsenious oxide, but it is likely to occur where there have been repeated attacks of poisoning extending over a few weeks. In the case of Mrs. Armstrong one of the nurses (Nurse Kinsey) described the appearance of the skin as being like that of a jaundice case, while the other nurse (Nurse Allen) said the skin was very dark and of a tawny colour.

There is no doubt that the hepatic function is diminished considerably as the result of the action of arsenic, and this accounts for the jaundiced appearance of the skin in protracted cases of arsenical poisoning.

In the Madeline Smith case (1857) Dr. Hugh Thomson, who saw the patient (L'Angelier) during life and who took part in the post-mortem examination, described the skin as being of "a distinctly jaundiced hue," both before and after death; in the joint post-mortem report of Dr. Thomson and Dr. James Stevens the skin is described as being of a tawny jaundice was due to arsenic, and in the evidence for the defence Dr. MacLagan stated that in arsenical poisoning there

is no jaundice. The victim in the Madeline Smith case probably had three attacks of acute arsenical poisoning during the last five weeks of life—namely, on February 19th and 23rd and March 22nd, the last proving fatal within a few hours. It is now fully recognized that arsenic is a powerful liver poison and so much damage may result that a condition of extensive atrophy (acute yellow atrophy) may follow. The action of arsenobenzol compounds (salvarsan, etc.) on the liver is well known, and in all acute fatal cases where death occurs within two or three weeks of its administration marked fatty degeneration of the liver occurs. Dr. Spilsbury has found this change in several such cases.

It is interesting to note that when the arsenical poison is given into the general blood stream, as in the intravenous administration of arsenobenzol compounds, the liver still acts as the first line of defence against the poison, and in fatal cases the bulk of the poison is found in the liver.

As a consequence of the fatty degeneration of the liver jaundice may occur, and a very large number of cases of salvarsan jaundice have been described. The onset of this symptom is usually late—weeks or months after the administration. As the jaundice clears up usually a definite shrinkage in size of the liver is found, though there is often some swelling present at its onset.

Salvarsan jaundice has been found associated with a defective hepatic function, and in a case under my care at St. Mary's Hospital two months ago the laevulose test for hepatic function, carried out by Dr. Roche Lynch, gave a very marked reaction indicating hepatic deficiency (see chart). Salvarsan jaundice is a serious symptom and not infrequently fatal, the condition of the liver often, at necropsy, showing marked shrinkage due to atrophy following the previous fatty degeneration (acute yellow atrophy).

Liver efficiency test. % of post-galyl jaundice. X = 50 grams laevulose given.

Renal Symptoms.

Arsenic is a powerful renal poison and acts on the kidney cells, causing fatty degeneration. Impairment of function of the kidney is shown by diminution or even suppression of excretion and the presence of albuminuria.

In the recent Black case albuminuria occurred during life, and fatty degeneration was found in the kidneys on microscopical examination after death. The kidneys also showed definite but not extensive arterio-sclerotic changes which must have been present before the onset of the arsenical poisoning. The action of the arsenic on the damaged kidneys so impaired their function as to be the direct cause of death.

In the Armstrong case albuminuria occurred during the acute illness of Mrs. Armstrong, and fatty degeneration of the kidneys was found by Dr. Spilsbury on microscopical examination. In 1920 a case of subacute arsenical poisoning due to arsenical fruit-spraying liquid was under my care; in this case persistent albuminuria with marked skin lesions occurred and death resulted after a long illness. Probably the lead present in the liquid accentuated the renal symptoms, but undoubtedly the marked albuminuria and other symptoms were mainly arsenical in origin.

Nervous System.

After a single poisonous dose of arsenic, unless this is large, nervous symptoms do not usually occur. Multiple neuritis may follow a single large dose. One instance of this has been described above. Another example came under my notice in Mesopotamia in 1916, where from accident a large quantity of drinking water became contaminated with sodium arsenite. A number of cases of acute arsenical poisoning resulted and in one a most severe arsenical neuritis followed.

In protracted acute arsenical poisoning due to repeated doses, multiple neuritis is a common symptom. It was marked in the case of Mrs. Armstrong, and in the Maybrick case some slight symptoms of neuritis occurred. The brain does not appear to be specially affected in acute arsenical poisoning, and usually the mental condition is unimpaired until a few hours before death.

As will be seen from the analyses of fatal cases, very little arsenic is found in the brain, and the cerebral symptoms in acute arsenical poisoning cannot be due to the direct action

of arsenic on the brain, but to the impairment of function of the other organs (liver, kidneys, and heart) and consequent indirect cerebral toxæmia.

Repeated Doses.

Where repeated doses of arsenic are given, as sometimes happens in criminal cases, symptoms of chronic arsenical poisoning (conjunctivitis, laryngitis, skin rashes and pigmentation—symptoms of multiple neuritis, etc.) may accompany the acute symptoms.

Fatal Dose.

A single dose of 2 grains of arsenious oxide has caused death in a healthy adult, and this is usually accepted as a possible fatal dose. It is common for much larger doses to be taken and recovery occur, owing, no doubt, to the rapid elimination of the poison by vomiting and diarrhoea. A given amount of arsenic if taken in solution and its administration spread over a short period is much more likely to prove fatal than if the whole amount is taken in one dose.

Fatal Period.

It is impossible to state this, since so many factors influence the time of death after a single fatal dose. Usually death occurs within three days, but in cases of repeated dosage death may not occur for many days. In one case after a large dose death occurred in twenty minutes; but in the case already mentioned after a dose estimated at 180 grains death did not occur for three and a half months.

Post-mortem Examination.

In cases where death has occurred some time previously careful search must be made for evidence of delayed putrefaction. This will be best shown by the condition of the internal organs. It is most marked in cases where there has been an illness prolonged over several days, the arsenic being widely distributed throughout the body; the drainage of the tissues consequent on the prolonged diarrhoea and vomiting also tends to delay putrefaction. In a case of illness where the diarrhoea is due to bacterial infection putrefaction will be accelerated, so that in this respect arsenical cases present a marked contrast.

Too much importance, however, must not be attached to delayed putrefaction, and in cases where a single dose only of arsenic has been taken and death has occurred quickly there may not be a marked delay. It depends on many factors—for example, the amount of arsenic distributed throughout the body, and the influence to which the body has been exposed after death, whether favourable or otherwise to putrefactive changes. The presence of inflammatory changes in the stomach and intestine should be carefully looked for, and especially the presence of petechial hæmorrhages. It is important to remember that, as the result of putrefaction, these signs rapidly disappear after death, and it may be quite impossible to detect them when death has occurred many days previously. In a case of exhumation the absence of inflammatory signs in the stomach and intestines is not indicative of the absence of arsenic. The presence of any solid particles of arsenic or of a pigmented powder must be looked for. Where putrefaction is advanced marked yellow staining may be found in the stomach or intestines, due to the formation of arsenic sulphide.

Careful reservation of the organs for analysis and microscopical examination should be carried out. The stomach, the small intestine, the caecum with the ascending colon, and the remainder of the large intestine with the rectum should be separated by ligature and placed in separate jars with due precaution. The contents of these should be kept separate, since the amount of arsenic in each may give an indication of the time of administration of the fatal dose. The liver, kidneys, heart, spleen, and brain should be placed in separate jars. In addition, a portion of muscle, a piece of bone, some hair cut off close to the scalp, a portion of skin, and the nails should be separately reserved in appropriate vessels. Any fluid in the coffin in an exhumation case should be reserved. Also, any earth adherent to the coffin or around it should be reserved for analysis. At the time of the examination small portions of the liver, kidneys, and heart should be placed in normal saline containing 10 per cent. formalin for future microscopical examination.

Chemical Analysis.

Too much importance cannot be attached to the methods employed in the analysis of organs for arsenic in suspected

poison cases. Only those methods should be used which are absolutely reliable and cannot give fallacious results.

As a qualitative test the Reinsch test is one of the most reliable. As a quantitative test where a weighable amount of arsenic is possible, a weighed portion of the organ is taken, the organic matter broken down by the usual method, and the arsenic precipitated as arsenious sulphide by treatment with sulphuretted hydrogen gas, the liquid being kept saturated with the gas for four days. The arsenious sulphide is filtered off, dried, freed from sulphur, and carefully weighed; its purity is confirmed by conversion into magnesium pyroarsenate, which is also weighed.

Where the quantities of arsenic present do not admit of weighing, a known amount of the organ is treated with nitric and sulphuric acids to oxidize the organic matter present. After evaporating off the acids the residue is submitted to the electrolytic Marsh-Berzelius test and the mirror obtained compared with the standard mirrors.

The above tests if carefully carried out are absolutely reliable. It is essential that all reagents should be free from arsenic, and control tests must be constantly done to ensure this. In toxicological work no test should be used which can possibly give fallacious results; for this reason I do not favour the use of the Gutzeit test, though it has been much used in pharmacological work.

The presence of traces of sulphide from putrefaction or of impurities in the chemicals used may lead to error. For the same reason the electrolytic test is to be preferred to the ordinary Marsh-Berzelius test.

It is particularly necessary that most accurate methods be used where only traces of arsenic are present in the material for examination, since the slight mirrors yielded in such cases might be produced by small traces of impurities in the chemicals used.

In toxicological work reliance should not be placed on a single method of testing—thus, if arsenic is found by the Marsh test, its presence should be confirmed by the Reinsch and other tests.

There have been instances in which arsenic has been found in the process of analysis of viscera, and the origin of the arsenic has been traced to the impure chemicals used. A very interesting example of such a mistaken diagnosis came to my notice in 1909.

M. F., a man aged 50, who lived in a large country house in the Midlands, and who was supposed not to have been on the best of terms with his wife, suffered from severe vomiting accompanied by some diarrhoea. The illness had lasted for four weeks, and during this time the wife was frequently in and out of the sick-room.

The patient had been addicted to alcohol for years, and even during his last illness took a fair amount of whisky, though not in great excess. The patient died, but before his death some suspicion rested on the wife, and in consequence the urine was collected and sent to a local pharmacist for analysis. The manner of collection of the urine was open to suspicion, and no especial care was taken as regards the cleanliness of the bottle or cork used. The urine was analysed by the Marsh test and a very large mirror of arsenic resulted. This mirror was much larger than would have been given by urine passed by a patient who had recently received a fatal dose of arsenic, and this of itself aroused my suspicions as to the danger of drawing any conclusions whatever from this piece of evidence. The presence of arsenic in the urine had not been confirmed by the Reinsch or other tests. The death of the patient resulted within two days of the collection of the sample of urine.

A post-mortem examination was made, and the organs were examined and analysed by me. The liver was greatly increased in size and of canary-yellow colour; microscopical examination showed that the cells were engorged with fat. No trace of arsenic was present in the liver or any of the organs of the body. The liver was in a state of very marked fatty cirrhosis due to alcohol, a condition commonly associated with most severe vomiting and a certain amount of looseness of the bowels. It is also commonly associated with symptoms of peripheral neuritis due to alcohol, and a fatal termination is by no means uncommon. The clinical picture is almost exactly like that of arsenical poisoning, and in the case of M. F., where arsenic was said to have been found in the urine in large quantity, it was not surprising that a confident diagnosis had been made of acute arsenical poisoning, and that a sensational second Maybrick case was supposed to have arisen.

The fact that all the organs of the body were free from arsenic at the time of death, even though submitted to the delicate Marsh-Berzelius test, showed conclusively that the urine passed two days before death must have been free from arsenic, since had it contained any considerable amounts must have been present

It was clear that the arsenical mirror obtained on the analysis of the urine had come from some extraneous source, either from a dirty bottle or from impurities in the chemicals used in the analysis. The facts of the case were carefully explained to the jury, and a verdict of death from cirrhosis of the liver was found.

This case was an excellent illustration of the error with which a mistaken diagnosis of arsenical poisoning may be

made. It also emphasizes the necessity of taking the utmost care in analysis and collection of specimens, and the importance of relying neither on one test nor on the results of analysis of one organ.

In a fatal case of arsenical poisoning arsenic should be found in the liver, spleen, kidneys, and other organs of the body, in addition to being present in the gastro-intestinal tract.

Elimination of Arsenic.

In acute arsenical poisoning the vomit and faeces will contain arsenic in amount depending on the quantity of the poison taken. The absorbed arsenic will be found in the blood and serous exudations.

Thus in one case the blood collected one hour after the injection of 0.6 gram of salvarsan contained 0.5 mg. and in another 0.33 mg. per 100 c.cm. The blood will contain traces of arsenic as long as the poison is present in the liver and organs; in fatal cases the blood and serous exudations contain appreciable amounts of arsenic. The urine after the administration of arsenic will contain arsenic for several days. After medicinal dosage, usually at the end of fourteen days, arsenic cannot be detected in the urine, but I have found definite evidence of arsenic twenty-one days after the administration of a single dose of salvarsan (0.5 gram). Where repeated doses of an arsenobenzol preparation have been given arsenic may probably be found in the urine for several weeks or even months.

Dr. Chalmers Watson recorded a case in the *Lancet*, April 22nd, 1922, where traces of arsenic were found in the urine and faeces fifteen months after a course of ten injections of novarsenobenzol, and Dr. D. R. C. Shepherd recorded a case in the *Lancet*, December 17th, 1921, where arsenic was found in the urine 111 days after a course of seven injections of neo-salvarsan. In the beer poisoning epidemic arsenic was found in the urine by Dr. Dixon Mann in one instance fifty-nine days after admission of the patient to hospital.

It is probable that during the prolonged administration of arsenic a certain amount becomes deposited in the skin, hair, and nails, and that this is gradually reabsorbed, being excreted by the urine and faeces; hence the poison may be found for long periods after the administration. Usually in acute arsenical poisoning after a single dose arsenic ceases to be found in the urine and faeces after about three weeks. The late Dr. Dixon Mann, who had a very extensive experience of the toxicology of arsenic, wrote in his textbook:

"In cases of acute arsenical poisoning it is very exceptional to find arsenic in the urine longer than a week or ten days after the administration of the poison; and in those fatal cases in which the patient survived more than ten days arsenic has rarely been found in the tissues."

I believe from my own experience that this still holds true in the majority of cases of acute arsenical poisoning arising from the taking of a single dose by the mouth.

Arsenic has a strong affinity for the keratin tissues, and hence it is found in the hair, nails, and skin, especially in cases of prolonged administration. In the hair it is deposited in proximal portions which represent the growth during the period absorbed arsenic is in the body. The sweat and sebaceous secretion during this period will contain arsenic, and as the whole length of the hair comes in contact with these secretions the limitation of arsenic to the proximal portions of the hair is relative not absolute. The analyses in the Armstrong case illustrated this point. In the Seddon case Sir Edward Marshall Hall quite rightly raised the question of why arsenic should be present in the distal portions of the hair if the case was one of acute poisoning as suggested. In this case the distal hair had been lying in blood-stained fluid in the coffin, and as this fluid contained definite traces of arsenic I gave it as my opinion that the arsenic in the distal portions of the hair had been absorbed from the fluid in the coffin. The accuracy of this statement was confirmed by soaking some arsenic-free hair in the blood-stained arsenical fluid for twenty-four hours and then thoroughly washing it in water, alcohol, and ether, and submitting it to analysis. It was found that an appreciable amount of arsenic had been absorbed by the hair, thus explaining the presence of arsenic in the distal portion of the hair from the deceased.

Arsenic may be found in the sweat, saliva, and bronchial secretion in acute arsenical poisoning, and it has also been found in the milk of lactating women. In two cases where salvarsan was given to patients during lactation I found arsenic to be absent in samples of milk taken from five and

a half to seventy-two hours after the administration, so that the benefit to the child resulting from the administration of salvarsan to the mother cannot be due to the presence of arsenic in the milk but to other causes.

TABLE I.

Patient E. M. Has taken liq. arsenicalis m 3 t.d.s. from November 28th to December 25th; m 5 t.d.s. from December 25th to January 1st inclusive; m 7 t.d.s. from January 4th to January 8th inclusive. All specimens were collected from 8 a.m. to 8 a.m.

Distribution of Arsenic in the Body in Fatal Cases.

This is well illustrated by the accompanying tables (VII to XIII). No rule can be laid down for the exact proportion of arsenic found in the various organs, since this will depend on the mode of administration, whether in one or repeated doses, on the time that has elapsed since the last dose, and on the state of health of the patient at the time of administration. The distribution of arsenic along the alimentary canal is of great importance because it gives a definite indication of the time at which the last dose was administered.

The routine examination of the alimentary tract by x rays after an opaque meal has given us definite knowledge of the rate of passage of the gastro-intestinal contents. Thus after twenty-four hours the bulk of the arsenic will have passed through the gastro-intestinal tract, as illustrated by the three Bingham cases. In the Armstrong case the large amount of arsenic in the caecum showed that a poisonous dose had been taken within twenty-four hours of death.

The liver, as has already been mentioned, rapidly absorbs arsenic, and usually considerable amounts are found in it, as is shown by the Armstrong and three Bingham analyses. In the Seddon case the amount was relatively small, while the amount in the muscles was high, probably owing to there having been a break in the repeated dosage. The large amount found in the intestines showed that a dose had been given within twenty-four hours of death.

Arsenic is usually found widely distributed through all the organs. The brain, however, contains only very small amounts, and I have found this to hold good, not only for poisoning by inorganic arsenic, but also for the organic arsenobenzol compounds. Stevenson and Dixon Mann had a like experience. This explains the absence of cerebral symptoms in acute poisoning by inorganic arsenic, and also shows that

the cerebral symptoms in acute salvarsan poisoning are due to autointoxication and not to the direct action of arsenic on the brain. In acute arsenical poisoning very little arsenic is found in the bone, as illustrated by the Seddon and Armstrong cases.

Poisoning by Arsenobenzol Derivatives.

This subject has been dealt with by me in a paper published in the BRITISH MEDICAL JOURNAL, April 1st, 1916. The interest attaching to cases of acute poisoning by salvarsan and allied compounds is that here, instead of gastro-intestinal symptoms occupying the prominent position, it is the poisonous effects of the arsenical compound on the organs of the body which produce the fatal symptoms. The liver bears the brunt of the attack and is the organ to suffer most damage. In fatal acute cases marked fatty degeneration is found in the liver, and the kidneys and heart muscle also commonly show this change.

The symptoms of acute salvarsan poisoning exactly simulate those of icterus gravis, and they are in my opinion due to auto-intoxication from defective liver function consequent on the action of the poison on the liver cells.

Very extensive damage and impairment of function is necessary for fatal auto-intoxication to be produced, but these cases do occur, and the risk from salvarsan administration should always be borne in mind. Even when the poisonous effect of salvarsan is not so massive, yet in many cases the liver suffers from the effect of repeated doses, and this is proved conclusively by the frequent occurrence of jaundice due to liver damage. This jaundice may occur weeks or months after salvarsan administration and may be most serious.

I am of opinion that the toxic action of salvarsan compounds on the liver is not sufficiently borne in mind in the very extensive use of this drug at the present day. Professor Maclean has suggested that liver damage is less likely to follow salvarsan administration if the liver cells have stored in them a certain amount of glycogen, and he has recommended that danger may be avoided by taking glucose shortly before the drug is given. This precaution is undoubtedly of value, and it has been emphasized by the use of a drug having like effects on the liver—namely, chloroform in its production of delayed chloroform poisoning after anaesthesia.

I wish to express my sincere thanks to Mr. J. Webster and Dr. Roche Lynch for valuable and much appreciated help in the work connected with this paper.

THE BLOOD SERUM IN PERNICIOUS ANAEMIA.

WITH NOTES ON THE NATURE OF THE DISEASE AND ITS TREATMENT.

A Preliminary Note.

BY

E. M. BROCKBANK, M.D., F.R.C.P.,

HONORARY PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

Two years and a half ago, when making some observations on the phosphorus content of the corpuscles, clot, serum, and plasma of pernicious and other anaemias, I noticed that the colour of the plasma or serum of pernicious anaemia differed from that seen in the plasma or serum of any other anaemia or of normal blood. Since making the observation I have used it regularly in the diagnosis of pernicious anaemia and have found it a most useful and reliable, if not a pathognomonic, test of this anaemia.

By pernicious anaemia I mean a severe anaemia of unknown cause with high colour index, almost always above normal; arabinuria; a tendency to megaloblast formation; and leucopenia; or absence or great scarcity of blood plates (as seen on smears); and, judging from observations which are recorded in this paper, serum and plasma with special characteristics.

The serum in pernicious anaemia is always of a definite yellow colour, varying in tint from that of a cowslip to the deeper buttercup yellow of Canada balsam, whilst the serum of all other anaemias is much paler, and resembles straw-coloured water. The yellow colour is so distinct that it can be recognized in the serum or plasma if only two or three drops of blood are drawn into, and half fill, a small bulb made of thin glass with inlet and outlet of a narrow bore which can be closed hermetically by sealing-wax. Care must be taken not to heat the glass bulb and blood with the wax, for this would tend to haemolyse the blood; it is for this reason that sealing the ends of the bulb with heat is risky. For the past two years I have regularly carried these glass bulbs about with my blood slides, and used one in each

case of anaemia examined. The blood runs freely into the small bulb from a needle puncture (when it is held lower than the blood drop on the finger), and when the ends of the bulb are sealed I stand it upright, or if taken at a patient's house I carry it upright in a small box in a waistcoat pocket until serum and clot separate. The colour of the serum is then seen, and, judging from a score or more of cases of pernicious anaemia and twice the number of other anaemias—Banti's disease, the leukaemias, secondary anaemia from any cause, purpura haemorrhagica—a diagnosis of pernicious anaemia from any other anaemia can be made. I have not applied the test to the anaemia of intestinal parasites which simulates pernicious anaemia, as I have never had any case of the condition under my care. A very important point is that serum from cases of severe secondary anaemia is pale straw colour, not yellow, in all the cases I have tried, whether due to septic infection, haemorrhage, or concealed malignant disease, which all have a high colour index (though not above 0.9) and a microscopic red blood cell appearance simulating pernicious anaemia but with leucocytosis. The blood in these severe secondary anaemias is specially referred to in the diagnosis of pernicious anaemia by Gulland and Goodall.

This serum bulb test is very simple and has been a most useful aid to me many times in the diagnosis of the type of anaemia under investigation. In its average appearance I can tell from the serum alone, and without the estimation of the colour index or an examination of the blood film, whether I am dealing with a case of pernicious anaemia; but, of course, I always make and examine a blood smear, and wherever possible estimate the colour index as well. On some occasions I have had my clinical opinion of a case confirmed or altered on my way home in a train by the colour of the serum which has separated from the clot.

There is no question of any pink colour in the deeper coloured yellow serum—nothing whatever to suggest the presence of any trace of haemoglobin or haemolysis; nor is it of a bile pigment tint.

In taking larger amounts of blood from a vein haemolysis is liable to occur in health or disease if there is any trace of alcohol or distilled water in the syringe or needle. This is avoided by drawing 0.5 c.cm. of sterile 5 per cent. sodium citrate solution through the sterilized needle into the sterilized syringe, and withdrawing the piston to its full extent, thus rinsing the barrel of the syringe with the citrate solution, which is then expelled from the syringe. The needle is then put into the vein, and blood withdrawn. Finally, the blood is expelled gently into a sterile test tube, which is handled very gently and laid down in a sloping position to facilitate separation of clot and serum. The serum is pipetted away from clot without disturbing red corpuscles and then well spun in a centrifuge.

Every precaution is taken to avoid haemolysis. Some of my specimens were taken with dry Wassermann outfit needles direct into a dry sterile test tube without any syringe; some were taken with an oiled syringe by Dr. Loveday, who has been director of our clinical laboratory for many years, and is thoroughly experienced in the dangers of haemolysis and the methods of avoiding it.

At first I could find no reference to the colour of the serum in pernicious anaemia in textbooks of medicine and pathology or monographs on blood diseases. There is no mention of it in Hunter's monograph, in French's full article on pernicious anaemia in Allbutt's *System of Medicine*, or in Gulland and Goodall's book on the blood. In the last named work a suggestion that the increased haemoglobin index may be accounted for by the presence of haemoglobin in the serum is mentioned, but no evidence is advanced in support of it.

In the section by Lazarus (p. 20) on the clinical methods of blood investigation in *Die Anaemie* (Ehrlich, 1909) there is no reference to the colour of the serum. The only mention of it that I have been able to find is in Panton's *Clinical Pathology*, where it is said:

"The bile colour of some serums is more closely simulated by the greenish-yellow pigment present in the serum of nearly all cases of pernicious anaemia. A certain percentage of these cases are, in addition, actually jaundiced."

In none of my cases of pernicious anaemia has the serum had a greenish tint.

Cause of the Colour of the Serum.

A larger amount of serum than that obtained in the bulbs is necessary to make any observations on the cause of the colour; for this purpose 5 c.cm. of blood or more are withdrawn from a vein in the arm with the precautions already referred to. The colour of the blood serum and plasma in pernicious anaemia calls to mind the striking yellow colour of the fat in the body, and the question of any possible connexion between the two and of the colouring matter being a lipochrome naturally arises. There is also the possibility of the presence of some bile pigment in the serum even in cases in which there was no real jaundice. I therefore examined the serum with the spectroscope—using a simple pocket or straight vision instrument—and immediately saw two very distinct absorption bands in the position of those of oxyhaemoglobin, and a much less distinct narrow third band farther to the right in the green in some specimens. These absorption bands appeared in all the specimens of pernicious anaemia serum or plasma examined except the very pale ones. This difference may be due possibly to the small quantity used, but possibly, as I believe, to there being more than one form of the disease. In the deeper coloured serum the bands are very distinct when the depth of fluid is only one-third of an inch and the shadows are about the same intensity as those of oxyhaemoglobin in 0.01 per cent. solution as depicted in Starling's *Textbook of Physiology*. I never saw any bands to the left of the D line in the red. In normal serum and

plasma, with their paler colour, I found the same absorption bands, though generally less distinct.

No modern work of reference that I know of has any mention of the presence of oxyhaemoglobin in normal serum. MacMunn and Thudichum refer to it and attribute the third band in the green to "lutein," which is probably a lipochrome.

Spectroscopic Observations.

With the help of Mr. Ernest Jones, M.Sc., M.B., my house-physician in 1920, the observations with the pocket spectro-scope were checked with a laboratory instrument with which we could measure the wave-lengths of the definite absorption bands. In all the cases examined these were identical with the absorption bands of oxyhaemoglobin—namely:

The band near	...	D 575 to 585
The band near	...	E 530 to 550
D line - 590	...	E line 530.

There was not the slightest indication of any absorption band in the red.

No absorption bands were seen in any other form of anaemia—Banti's disease; purpura haemorrhagica; septic anaemia; secondary anaemia from haemorrhage, malignant disease, or any other cause; the leukaemias—and, especially, I repeat, as a very useful point of differential diagnosis, that they were not present in those forms of anaemia, previously referred to, which simulate by their high colour index (for a secondary anaemia) and by their microscopic blood picture pernicious anaemia. The yellowness of the serum, which contained enough oxyhaemoglobin to give its characteristic absorption bands, was striking: there was no trace of pink tint in it.

Haemoglobin, in the small quantity seen microscopically in a solitary blood corpuscle, is yellowish. Many such yellow corpuscles together give the normal pink blood colour; but I have been unable to find any statement in textbooks of physiology or works on the blood that haemoglobin is ever yellowish in solution. I have diluted normal blood with water so much that I could see no colour of any kind in the fluid, but only in the meniscus at the top of a small test tube, and this was pink. The question as to whether haemoglobin in the serum of pernicious anaemia which was yellow existed in some new combination or solution then arose, but I came to the conclusion that the deeper yellow shades of the serum of pernicious anaemia are produced by a weak pink solution of haemoglobin strengthening a lighter yellow pigment, possibly that which colours all the tissues of the body, especially the fat. This is seen by examining a specimen of the serum with the naked eye in the dark by artificial light. The dominant yellow colour is then less visible, whilst the haemoglobin is seen faintly pink, like weak laked blood, and not in the least brown.

The Nature of the Yellow Pigment.

It is difficult to carry out accurate chemical investigations with the small amount of serum which can be obtained from a case of pernicious anaemia, but Mr. Jones applied standard tests to some cases. He found that the yellow colouring matter of the serum was not extracted by ether. It remained after hydrolysis with alcoholic potash and subsequent precipitation of fatty acids by hydrochloric acid.

These two results suggest that the colouring matter is not a lipochrome. It is precipitated by reagents which precipitate proteins. This observation of Mr. Jones is interesting in view of the fact that a protein rein when injected into the bone marrow produces blood appearances like those of pernicious anaemia. The identification of the pigment which colours the fat and other tissues might give a useful clue to the causation of the disease.

I have been unable to find any reference in recent English literature or textbooks to the spectroscopic examination of the blood serum of pernicious anaemia, and consequently of the absorption bands found therein. The classical work on the *Spectroscope in Medicine*, by MacMunn (1880), and *A Manual of Chemical Physiology*, by Thudichum (1872), though valuable and interesting, are out of date, especially in the nomenclature of the haemoglobin derivatives. I accordingly wrote to Sir Archibald Garrod, with whom I had previously had some correspondence about the spectroscopic appearance of the blood in eutero-genous cybosis. He kindly directed my attention to some work by Schumm in the *Zeitschrift für physiologische Chemie*, 1916, vol. 97. This observer recorded in this and previous volumes of the same journal his observations on haematin as a pathological constituent of the blood in certain diseases,

including pernicious anaemia. He gives references to similar observations by Schottmüller in the *Münchener medizinische Wochenschrift*, 1914, No. 5, and by Hijmans van den Bergh and Snapper in the *Berliner klinische Wochenschrift*, 1915, No. 42. Schumm worked with a grating spectroscope and took photographic records of the spectra.

All these observers pay a great deal of attention to haematin as the chief spectroscopic feature of the serum of the various diseases, including pernicious anaemia, investigated by them, and say very little about the presence of haemoglobin, and, as far as I have seen, nothing about the colour of the serum. Schumm does refer to the brownish colour of any solution of haematin. After getting as far as this I was introduced by letter to Professor A. A. Hijmans van den Bergh of Utrecht by Sir Archibald Garrod, and he kindly offered to examine a specimen of the serum which I obtained from my patients. I sent him one, and received the following comments in reply, which I have his permission to print:

"I believe that the colour of the serum which you kindly sent me is due to a small increase of the bilirubin content and to the (oxy)haemoglobin dissolved in the serum. There was no haematin to be discovered in this specimen.

"We generally find a moderate increase of the bilirubin in the serum of patients with pernicious anaemia, especially during the periods of intensive blood destruction. Whereas the normal rate is found at about 0.2 to 0.3 or 0.5 of our units, in pernicious anaemia we find 1 to 1.5 or even 2 units. In your specimen the bilirubin value amounted to 1 unit.

"Haematin is not always present in the serum of pernicious anaemia, not even during the period of going downhill. In this disease it seldom is present in such a quantity that the colour becomes brownish, but in exceptional cases this condition is met with. (In other diseases the quantity of haematin may be so large as to give a brownish tinge to the serum—as, for instance, in some cases of anaerobic sepsis.) The quantity of haematin being only very small in pernicious anaemia, you will very seldom find a band in the red region of the spectrum. We demonstrate the haematin by adding ammonium sulphide, whereupon the very dark bands of 'haemochromogen' appear. (As they disappear rapidly, one has to look immediately after having added the sulphide or whilst an assistant adds it before the spectroscope.) But, as I have mentioned already, in your specimen there were no traces to be found, even in this way.

"Now as to the presence of the haemoglobin in the serum. This point is a very difficult and important one. We should be very careful, of course, in drawing conclusions from it. For it is always possible that the haemoglobin has escaped from the corpuscles because of the manipulations during and after collecting the blood. Therefore we always take the most careful precautions that we can for preventing artificial haemolysis (dry and warmed tubes, no shaking of the tubes, careful centrifugalizing, etc.).

"Might it not be possible that the presence of haemoglobin in the serum in your cases of pernicious anaemia is due to artificial haemolysis? For in our cases I do not remember to have found more haemoglobin than can be met with in every normal serum. Perhaps we did not look at it with sufficient attention. I must confess that the supposition of an artificial haemolysis as a cause of the presence of haemoglobin in your specimens of pernicious anaemia cannot explain the curious fact that you never find it in other anaemias.

"Theoretically, of course, it is quite intelligible that a slight intravascular haemolysis should occur in patients with pernicious anaemia. I think it would be of the greatest interest to repeat your experiments with the most careful precautions. I hope you will succeed in bringing this problem into clearness. I shall pay attention to it and let you know the results of our observations."

After receiving the letter I took blood from a patient with a sterilized and perfectly dry Wassermann outfit needle and rubber tubing, letting the blood flow into a paraffined test tube. This was carefully placed in an inclined position and the serum separated well; it was perfectly clear and of yellow colour. It was withdrawn by pipette introduced well away from the clot and well centrifuged. The oxyhaemoglobin bands were there as before. I could not get the haemochromogen bands by adding ammonium sulphide. This suggests that my previous methods were equally careful. I have purposely avoided the immediate treatment of the blood in a centrifuge, fearing that some traumatic haemolysis might be caused.

When the yellow serum of pernicious anaemia is kept in sealed tubes it begins to lose its colour in a few days, and by the end of a week the absorption bands of oxyhaemoglobin become much less clear and eventually indistinguishable. In one case it turned to a light cherry colour after being kept in a sealed tube a couple of months, and gave a spectrum of haemochromogen. I could not understand what had happened when the serum lost its colour and the bands of oxyhaemoglobin until I heard from Professor Hijmans van den Bergh of his methods of identifying haematin by reducing it with ammonium sulphide and production of haemochromogen. It

then became quite clear, especially when it is remembered that the spectrum of haemochromogen will appear in dilution of 1 in 25,000, and that its formation is even a more delicate test for blood than the spectrum of oxyhaemoglobin itself.² The explanation of the loss of colour in the sealed tubes seems to be that the oxyhaemoglobin changes to haematin in time, and this in weak solution does not deepen the colour of the serum to the same extent as the haemoglobin does. This explanation I put to the test by unsealing an ampoule of serum which I had kept for a couple of months, and which, from being quite yellow and giving good oxyhaemoglobin bands when fresh, had become pale and showed no spectrum. On adding to this some ammonium sulphide I obtained a very clear absorption spectrum of rarer than that of oxyhaemoglobin had change to the cherry red in the ampou o the oxyhaemoglobin being changed to haematin, and this body being further changed, probably by decomposition, to haemochromogen, which has a cherry-red colour in solution, haematin being in the same strength nearly colourless.

Professor Hijmans van den Bergh says that he has not paid much attention to the oxyhaemoglobin in pernicious anaemia serum, being chiefly interested in the haematin. It is possible, however, that the haemoglobin is the forerunner of the haematin and its presence in the plasma in the blood vessels the essential feature of pernicious anaemia. Some haemoglobin compound most probably does circulate in the plasma ready to be deposited as haemosiderin in the liver. An explanation of the difference in my results and those of other Continental observers may be that there is more than one variety of pernicious anaemia, and clinical appearances of the disease, in my opinion, support this view.

In two or three of my original cases in which the serum was rather orange-coloured I found the oxyhaemoglobin bands more distinct than usual, but only in one, which I met with quite recently, have I seen a band in the red. I did not try Professor Hijmans van den Bergh's method of getting the haematin bands until the last month because I did not know of it earlier. I failed to get haemochromogen by adding ammonium sulphide in the ordinary way.

The fact that oxyhaemoglobin occurs in the serum of cases of pernicious anaemia obtained from the vein of a living person and separated from the clot in a test tube is, of course, no proof that the oxyhaemoglobin is present in the plasma of the circulating blood. It is quite possible that in spite of every precaution taken to prevent it some haemoglobin escapes from the red corpuscles during the process of withdrawal of blood from a vein; but even if artificial haemolysis does occur this does not affect the fact that oxyhaemoglobin appears in the serum of pernicious anaemia, but not in that obtained by identical methods and with identical precautions from any other form of anaemia. There is, however, some reason to think that oxyhaemoglobin does exist in the plasma of the circulating blood. It is an unquestioned fact that the red corpuscles in pernicious anaemia carry, on the average, more than the normal amount of oxyhaemoglobin, sometimes as much as 1.5 times this amount; and it is quite possible that more oxyhaemoglobin is manufactured in pernicious anaemia than there are red corpuscles to carry it, and that some circulates free in the plasma. In pernicious anaemia there is not such a deficiency of oxyhaemoglobin as there is in an anaemia of low colour index and low blood count.

Is Pernicious Anaemia a Malignant Disease of the Blood?

Pernicious anaemia may be a form of malignant disease of the blood—that is, a reversion to embryonic type of blood and blood formation. The scarcity of blood plates with such evidence of red-marrow activity always strikes me as peculiar. At most, the blood plates number very few, as compared with normal blood, and are insignificant as compared with the enormous numbers found in some cases of secondary anaemia, such as that due to moderate haemorrhage, chronic nephritis, and cancer. In some cases of pernicious anaemia scarcely any can be seen. As blood plates contain nuclein and resist peptic digestion, they are probably the remains of the nucleus of the bone-marrow erythroblast. Their presence, and that of nucleated red cells, is, in my opinion, an indication of an attempt by the bone marrow to regenerate red blood corpuscles, and when they occur the prospects of improvement in pernicious anaemia, temporarily at any rate, are good. But their small number conveys the impression that, with all its apparent activity, judged from its appearance, the marrow in pernicious anaemia is not pro-

ducing red cells well, and this raises the question, Are the being produced anywhere else? Some justification for the question is to be found in the resemblance which the megakaryocytes, microcytes, and poikilocytes of the disease have to similar forms met with in embryonic mammalian blood, as described by Emmel.³ His observations are striking, and in my opinion support the view that in pernicious anaemia there is a reversion to embryonic type of blood and blood formation. I hope at a later date to go more fully into this question and discuss the bearing which the scantiness of blood plates has on the nature of the disease.

Treatment.

In conclusion, I may refer briefly to the very remarkable improvement which generally takes place for a longer or shorter time when pernicious anaemia is treated by liquor arsenicalis in graduated doses. I always begin with 4 minims three times a day after food, and increase the dose by one minim every forty-eight hours until 8 minims for each dose are being taken. Then by a similar se i dose the original 4-minim dose is ! later the arsenic should be stopped au then the same graduated course of treatment carried out again. The patient should be kept in bed and in the open air as much as possible and have well-ventilated room. Arsenic should be given in this way on and off for several months. When there is any cardiac muscle failure, with dilatation of the heart and oedema, as there often is in pernicious anaemia, digitalis in doses of 1/240 grain digitoxin (Nativelle's granule) daily in addition to the arsenic soon brings about a wonderful improvement; and I have seen patients with both feet in the grave recover in six weeks comparative health and activity. They all tend to relapse, however. Very few patients suffering from pernicious anaemia cannot take liquor arsenicalis. Occasionally I have given it even when vomiting and diarrhoea were present when the case first came under observation, with improvement in the symptoms.

Conclusions.

1. The serum of pernicious anaemia is always definitely yellow and that of all other anaemias nearly colourless. The colour may be seen in two or three drops of serum in a small glass bulb.
2. Oxyhaemoglobin absorption bands appear in the serum of the great majority of cases of pernicious anaemia, and can easily be seen by a pocket spectroscope. They are not seen in the serum of other anaemias.
3. Continental observers have found haematin in the serum of some cases of pernicious anaemia, and they believe that bilirubin gives rise to the yellow colour.
4. There may be some free oxyhaemoglobin in the plasma of the circulating blood of the disease.
5. It is possible, judging from the serum, that there are at least two varieties of the disease.
6. Blood plates are generally very scanty or absent in the disease, but when present are a sign of potential regeneration of red cells by the bone marrow and indicate a good temporary prognosis.
7. The abnormal conditions of the red corpuscles suggest the possibility of pernicious anaemia being a malignant disease of the blood.

HIGH PERCENTAGE OF ABNORMAL OBSTETRIC CASES IN GENERAL PRACTICE.

BY

J. WALLACE ANDERSON, M.B., CH.B. GLASG.

From January 1st to June 15th, 1922, the percentage of abnormal obstetric cases met with in my practice has been unusually high. Out of a total of 42 cases attended, 18 (45.2 per cent.) have presented some definite abnormality. These cases occurred in the ordinary course of practice, only one having been seen on the requisition of a midwife. The abnormal cases were as undernoted.

1. Primipara, aged 34. Great oedema of feet and legs for one week before confinement; very slight albuminuria. On commencement of labour great headache and flashes before the eyes. One

eclamptic seizure during late second stage. Anaesthetic immediately commenced and continued for two and a half hours, during which time forceps delivery was done. Complete recovery of mother and child, although the latter had icterus neonatorum for a time.

2. Primipara, aged 35. Hyperemesis gravidarum throughout pregnancy, and albuminuria for several weeks towards end. Two days in labour, which was practically painless; early rupture of membranes; uterine inertia. Forceps delivery; mother very toxic for three days afterwards, but completely recovered. Child apparently well for three days, then died in a convulsion.

3. Primipara, aged 29 (sister of No. 2). Hyperemesis gravidarum throughout pregnancy, but never albuminuria. Forty-eight hours in labour; slight general contraction of pelvis. High and difficult forceps delivery. Both well.

4. Multipara, aged 34. Persistent occipito-posterior delivery; both well. Eighteen months previously had suspension of the uterus (after Gilliam) with posterior colpo-perineorrhaphy and trachelorrhaphy.

5. Multipara, aged 32. Albuminuria, headaches, and oedema for three weeks. Breech presentation at term; four hours' labour. Delivery under anaesthetic accomplished in less than five minutes; no prolapse of, or pressure on, cord by head; asphyxia pallida. Prolonged artificial respiration, and stimulation unfruitful. Recovery of mother, after being very toxic for first five days. At previous parturition, which was vertex, child was stillborn at term, without apparent reason.

6. Multipara, aged 26. Twins—one vertex, one breech. All well.

7. Primipara, aged 20. On first examination, os fully dilated, and flat pelvis discovered. No presenting part felt. Spontaneous rupture of membranes in a few minutes, followed by unaided and rapid delivery of an anencephalic monster, which survived for a few minutes only. Mother well.

8. Multipara, aged 29. Sudden haemorrhage without pain, at or near term. Marginal placenta praevia. Vagina packed twice under anaesthesia, with interval of twenty-four hours. Forceps delivery later. Both well.

9. Primipara, aged 26. Profuse haemorrhage at seven months, followed by labour. Central placenta praevia. Rapid delivery of stillborn foetus. Recovery of mother.

10. Primipara, aged 22. At six and a half months urine loaded with albumin, headaches, and sickness with flashes, but no oedema. Three weeks' rigid treatment, without improvement. Induction by bougies. Delivery in seven hours of a living child (breech), which, despite prematurity and icterus, has done well. Mother well, but still has some albumin.

11. Primipara, aged 22. Face presentation. Delivered herself in about twelve hours. Both well.

12. Multipara, aged 34. At six months, urine clear; at eight months, loaded with albumin, and very great oedema of face and legs. Abdomen notably enlarged. Rest and milk diet. Two days later, sudden large haemorrhage, followed by labour, and delivery of triplets, weighing 6½, 3½, and 3 lb. respectively. Mother and three children all well so far. At last parturition had placenta praevia, since when she has had an abortion, followed by dilatation and curettage.

13. Multipara, aged 25. Urine clear of albumin on several examinations before and at eight months. Natural delivery of living child at term. Oedema of legs and eyes noticed at labour. Child unnaturally quiet, and died twenty-four hours later. At previous confinement had a macerated full-term child.

14. Primipara, aged 39. Amenorrhoea for four months, with sickness for latter two months. Abdomen enlarged to above umbilicus, with colicky pains. Hydatidiform mole partially extracted manually and stage nine days later, to complete the evacuation of uterus. Well to date.

15. Primipara, aged 30. Three weeks beyond calculated term. Intermittent labour for three days before being seen. Slight general contraction of pelvis (conjugate about 3½ inches). Large head felt, freely movable above pubis. Twenty-four hours later soft like membranes presenting, but still no Caesarean section. Living child weighing 9½ lb. Both well.

16, 17, 18, and 19 were cases in which delivery had to be completed by forceps and chloroform, owing to the length of the second stage.

Analysis of the Series of Cases.

1. As already stated, out of 42 cases, 19 (45.2 per cent.) presented some definite abnormality.
2. Of the 15 detailed cases, 9 (60 per cent.) were primiparae.
3. Of the 15 detailed cases, 7 (46.7 per cent.) were toxæmias of pregnancy (four were in primiparae).
4. Of the 15 detailed cases, the average age was just over 29.

Note.—One of the normal cases in the series was a patient whose first pregnancy was twins (with survival of both), whose second pregnancy was tubal, with consequent laparotomy and removal of one tube and ovary, and whose present (and third) was normal.

I wish to acknowledge my indebtedness to my assistant, Dr. P. B. Farrar, for his collaboration with me, both in the conduct of the cases and in extracting the details and statistics from my case-book.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ALCOHOL IN ITS RELATION TO DISEASE.

The facts here stated are the outcome of observations made on a series of 150 cases treated in the medical wards of the London Temperance Hospital; they include 75 non-abstainers and 75 abstainers.

In a series of 76 cases of acute lobar pneumonia it was observed that the number of deaths among the 38 non-abstainers was proportionately greater. In these also relapse was found to be more frequent, and the disease ran a much more severe course. The temperature reached a greater height, with a tendency to fall by lysis and not by crisis. There was either leucopenia or a very negligible leucocytosis, showing that the resistance of the tissues to the infection was poor. Dilatation of the heart was more frequent and supervened earlier. In several cases there was a tendency to complications (pericarditis, otitis media, and pneumococcal arthritis). In those cases which recovered the convalescence was slow, there were irregular rises of temperature during convalescence, and the heart remained irritable in response to effort.

In a series of 30 cases of influenza, the tendency to post-influenza bronchopneumonia appeared to be more marked in the 15 cases that were non-abstainers, the heart was similarly more affected, and noisy delirium often supervened.

Of 20 cases of chronic Bright's disease, with high blood pressure, half were habitual drinkers, and in these damage to the kidneys appeared to be proportionately greater, and it was with difficulty that one could appreciably lower the blood pressure.

In a series of 24 cases of valvular disease of the heart, among the 12 who were non-abstainers it was found that failure of compensation ensued comparatively earlier, and there seemed to be a lack of the normal "reserve power" of the heart musculature, and hence dilatation, and in a few cases failure of the heart ensued before any evident muscular hypertrophy could take place, as was confirmed *post mortem* in the cases that reached a fatal termination.

One cannot help being convinced from these observations that there must be a substratum of truth in the oft-repeated statement that habitual indulgence in alcohol is demoralizing to the system, and tends to lower the normal powers of resistance of the tissues to microbial toxins. On the other hand, I have been equally impressed with the part alcohol has played in two cases of grave collapse and impending "cardiac distress" which I came across in private work. In these I found that hypodermic injection of 10 minims of brandy had an almost miraculous effect in reviving the patient after an injection of digitalin and strychnine had failed. Facts like these equally lead one to hold the view that, in the light of our present knowledge, the time for scrapping alcohol as a valuable therapeutic adjunct has not yet arrived.

P. GANNHY, M.B., M.R.C.S.,

Late Medical Registrar, London Temperance Hospital.

BUBONIC PLAGUE TREATED WITH NEO-SALVARSAN.

In India as a whole plague is endemic. In the North-Western and the North-West Frontier provinces it breaks out in the epidemic form, usually in the spring of every year, and lasts well up to the commencement of summer. If even in June or July there is a heavy rainfall, the epidemic has been known more than once to recur with a high mortality.

Prophylactic treatment by vaccines confers immunity for a very limited period, and even then the results are not very encouraging. Some years ago, in a small village in the Punjab, inhabitants were inoculated with vaccine, but unfortunately more than three-fourths died.

So far, we have no reliable serum for curative treatment, and in my opinion the failure is due to the fact that serum-yielding animals—namely, horses, cattle, and goats—are naturally immune to the disease. Plague being a disease of rats primarily, if amongst the rodent tribe we could find a big enough animal to yield an adequate amount of serum, it is probable that a serum as efficient as that for diphtheria or tetanus may be prepared.

Bubonic plague being septicæmic, it seems pathologically reasonable (in theory at least) to assume that if a drug were

introduced into the circulation which would destroy *Pasteurella pestis* and yet not harm the cells of the body, it would have a beneficial effect on the course of the ailment.

A young man, about 22 years of age, had a prominent painful bubo in the left groin, and fluid taken from this bubo proved positive for *B. pestis*. The patient was seen by me on May 11th, three days after the onset of the disease; his temperature was 104° F. at that time. At 3 p.m. I injected 0.45 gram of neo-salvarsan in 10 c.cm. distilled water intravenously, and 0.5 c.cm. pituitary extract subcutaneously. That very evening the temperature commenced to fall by lysis, and the symptoms (headache, sinking feeling, and restlessness) began to abate. On May 15th the temperature was 100° F., and on May 16th it was normal. The patient, except for the usual debility after the disease, is now quite well. The bubo was treated by the application of belladonna and glycerin.

The efficiency of the treatment cannot be strictly stated to be conclusively proved, yet the benefit shown in one case even may reasonably encourage further trial.

When going to a case of plague I always wear long boots over the trousers up to the knees, and anoint my hands, arms, and neck with eucalyptus oil. I refrain from scratching an insect bite, but bathe it with carbolic lotion 1 in 20, followed by the application of eucalyptus oil.

Peshawar City, India.

Reviews:

THE PHILOSOPHY OF SUCCESS.

UNDER the title *Some Things that Matter*,¹ Lord RIDDELL, so well known as a newspaper proprietor and representative of the British press at the Peace Conference, has brought together a series of articles which he contributed to *John o' London's Weekly*, on concentration, observation, thought, reasoning, and other mental qualities. These essays have attraction as conveying part at least of the philosophy of a shrewd student of affairs as well as a reader of books, who, happening to have been trained professionally as a lawyer, also looks at matters with a severe sense of practice and utility.

Lord Riddell would be the first to acknowledge that the conditions of their original publication have tended to make these contributions rather fragmentary, though none the less well worth reading. The first article, for example, is excellent, even if unintentionally humorous, in its Sandor-like recommendations for exercising the mind with "brisk, vigorous concentration for a quarter of an hour a day, extending to two hours a day by the end of the month," and it is, of course, quite sound in its reminder that the habit grows with interest, and that the interest may be increased with the habit: this is what the essay amounts to. But such a view must not be taken too absolutely, and might with advantage be expanded. Lord Riddell cites as his text Emerson's words, "Concentration is the secret of success." That is true enough so far as it goes, but mere concentration without the cultivation of mental initiative will not carry far. One of our greatest psychologists has pointed out that though restless men may prove to be failures, the most successful of human beings are men who in certain respects are prodigiously restless. The considerations are complementary to each other.

In writing on "Observation" Lord Riddell will probably surprise many of his readers by his disclosure of the lack of accuracy amongst educated persons. He gives as an illustration a test made in a university class. Dr. Munsterberg has related similar tests amongst professional men, including, if we remember rightly, a selected body of lawyers. It is desirable to urge development of all the senses; but apparent weakness may be due to preoccupation in other mental concerns. Lord Riddell, going on to advise young men "How to read," shows that his own groundwork was law books, and that by their study he learnt to judge the value of evidence. This capacity he holds to be one of the most valuable qualifications in life, and there is great force in what he says on this point. For that matter he might also have recommended some scientific books, for they have to be understood to be read at all, and this tends to clarity of definition. Himself an able controversialist and witty after-dinner speaker, Lord Riddell is quite at his best in dealing with the art of public speaking, recognizing, though he does not put it in these precise words, that it should make a

threefold appeal—to the intellect, to the emotions, and to the will.

Other articles under various headings treat of circumstantial evidence, of logic, of relevancy, and of legal maxims. They form easy reading on what some are inclined to regard as dry subjects. They will doubtless be liked the better because the writer has drawn upon his store of anecdotes for illustrations. Sagaciously, too, he makes no claim to sum up the rules of action and conduct. His book is entitled "*Some Things that Matter*," not "*The Things that Matter*," and so he runs no risk to reputation by this adventure into authorship. The volume is not designed as a guide to life.

TAYLOR AND POULTON'S "MEDICINE."

Taylor's *Practice of Medicine*² first appeared in 1890. The twelfth edition has been wisely and extremely thoroughly edited by Dr. E. P. POULTON, who, recognizing that it is now beyond the power of an individual to cover the whole field of medicine, has delegated to Dr. C. P. Symonds the section on nervous diseases and to Dr. H. W. Barber the responsibility for the account of skin affections. It may be remembered that in Hilton Fagge's *Medicine* (1886) two parts—namely, those on valvular disease of the heart and on cutaneous diseases—were left unwritten by the author and were provided by the late Sir Samuel Wilks and the late Dr. P. H. Pyo-Smith.

Although it is only four years since the late Sir Frederick Taylor brought out the eleventh edition of his book, the present volume has undergone very considerable changes, as is shown by the addition of twenty-four new articles, and by the large number that have been practically rewritten. Of the twenty-four plates, of which twenty are radiograms and four sections of the spinal cord, nineteen are new. The revision has been remarkably successful and complete, and as evidence of its up-to-date character attention may be drawn to the inclusion in the appendix of van den Borgh's tests for bilirubin in the blood serum, with a reference to Dr. J. W. McNece's contributions to the subject in our columns so recently as May 13th last. The diseases of metabolism and those of the endocrine glands are considered together in a section prefaced by a short summary, which the editor is so specially fitted to contribute, of basal metabolism; the account of diabetes mellitus follows and is naturally both full and up to date, due credit being given to Dr. George Graham for the independent initiation of the method of treatment associated with Allen's name. Obesity is dealt with in this section, but gout comes under the diseases of joints next to infective arthritis. The tests for renal and hepatic function are described, and throughout the volume the clinical tests and methods of investigation are clearly outlined. Encephalitis lethargica, one of the new articles, is placed between acute poliomyelitis and hydrophobia and has been written by Dr. C. P. Symonds, who, as mentioned above, is responsible for the diseases of the nervous system; and Dr. J. J. Conybeare has revised and rewritten many of the articles on tropical diseases.

Dr. Poulton is to be congratulated on having admirably maintained the character of this successful work for students, whether qualified or not, of medicine.

NON-SPECIFIC PROTEIN THERAPY.

In a review of his book *Hormone Therapy* (British Medical Journal, 1922, i, p. 955) it was said that the author, Dr. D. Montgomerie Paton, had for twenty-three years treated various diseases by the oral administration of antidiaphoretic serum, and in a letter published on July 1st (p. 29) Dr. Allison of Newcastle-on-Tyne stated that he had employed the method since 1892, more than thirty years ago. Nevertheless the conception of non-specific protein treatment did not attract much attention until six or seven years ago. As Dr. W. F. PETERSEN of Chicago has had considerable experience of the method, to which attention has from time to time been directed in our columns, his *Protein Therapy and Non-specific Resistance*,³ with its comprehensive review of the whole subject, is most welcome. The natural prejudice against non-specific therapy—for example, the treatment of

¹ *Some Things that Matter*. By Lord Riddell. London: Hodder and Stoughton, Ltd. 1922. (Demy 8vo, pp. 187; one portrait. 7s. 6d. net.)
² *Taylor's Practice of Medicine*, twelfth edition. By E. P. Poulton, M.D., F.R.C.P. London: J. and A. Churchill, 1922. (8vo, pp. 30s. net.)
³ *Protein Therapy and Non-specific Resistance*. By W. F. Petersen, M.D.; with an Introduction by J. L. Miller, M.D. New York: The Macmillan Co. 1922. (Med. 8vo, pp. xvii + 314; 27 figures. 21s. net.)

gonococcal arthritis by typhoid and paratyphoid vaccine—as an illogical and haphazard method which opens the door to quackery has been forced to give way before the clinical results that are so striking and incontestable as to necessitate a broadening of our views on the problems of immunity. The non-specific reaction does not, of course, bring into play any new factor of resistance, but it deals with the stimulation of the forces of resistance by various substances, such as vaccines of bacteria other than those infecting the patients, milk, poptone, nuclein, and by other methods, such as the injection of colloidal metals, lipoids, enzymes, fixation abscess, heliotherapy, and even the old method of counter-irritation. Usually these bodies induce a general reaction, manifested by rigor, fever, and leucocytosis, the beneficial effect being often, but by no means invariably, in proportion to the reaction. Protein therapy is sometimes spoken of as “shock,” “foreign protein,” “colloid,” or “hetero-vaccine therapy”; but v. Groer’s term “ergotropio” is possibly more correct, inasmuch as it emphasizes the reaction of the patient and ignores the causal agent of this reaction. Dr. Petersen describes the general and the focal reactions that follow non-specific therapy, and then proceeds to epitomize the various theories put forward by Weichardt, Döllken, Nolf, and others as to the mechanism of the reaction, the mobilization of enzymes after injection being fully considered. In the chapter on the indications and contraindications of non-specific treatment it is pointed out that the method is purely one of stimulation, whereby the forces of cellular and humoral resistance are for a short time keyed up to the very highest pitch. The treatment is therefore “naturally” most effective at an early stage of infection before the cells of the body have become exhausted; the injections should be given slowly and the first dose should be relatively small. The author insists that this form of treatment should in no circumstances be considered as a rival or as a substitute for available specific measures of proved value. The clinical results of non-specific treatment of a large number of diseases are described in successive chapters devoted to arthritis (on which very considerable benefit has been obtained), typhoid and other infections, spirochaetal and protozoan infections, and miscellaneous affections. This work is clearly written, provided with an extensive bibliography, and supplies a definite want.

Professor DANYSZ, of the Pasteur Institute, Paris, is well known as a writer on what may be called the philosophy of pathology, and a few years ago we devoted a good deal of space to a book by him on the principles of the evolution of infectious diseases (BRITISH MEDICAL JOURNAL, September 21st, 1918, p. 323). This book has now been translated into English and condensed by Dr. F. M. RACKEMANN, and published with a very long title (transcribed below) which may here be abbreviated to the *Evolution of Disease*.⁴ The subject is complicated and in spite of all the translator has done the difficulties of the presentation of the problems with which it deals remain to strike the reader. The first of the two parts of the book sketches the theories of immunity associated with Metchnikoff and Ehrlich’s names, and gives the present day conception of immunity in the most general terms as a necessary reaction of the whole organism against each and every substance which is not a part of the organism when introduced into its interior in any manner. These substances fall into two groups: (a) the colloids, which after an incubation period produce specific antibodies in excess, and (b) crystalloids, which do not give rise to specific antibodies. Normally colloids when taken by the mouth are changed by gastro-intestinal digestion into amino-acids and thus absorbed, but when colloids pass into the circulation from failure of the alimentary canal or in other ways—for example, by hypodermic injection—the tissue cells have to undertake the process of digestion, and this leads to the formation of antibodies in excess and to anaphylaxis which should be regarded as a pathological reaction of the process of immunity, and as the cause of symptoms in infectious disease. Thus in enteric fever the anaphylactic crises last for weeks, a condition of actual anaphylaxis different from latent anaphylaxis in which the organism is surcharged with antibodies as the result of previous ingestion or injection of the antigen or as a result of remission of diseases with relapses and with long evolution, such as tuberculosis, syphilis, trypanosomiasis, and malaria. Anaphylactic shock or crises can be prevented

by anti-anaphylactic inoculation, which leads to progressive neutralization of the antibody excess; this beneficial effect can be obtained not only by the injection of the original antigen, such as an autogenous vaccine, but by non-specific protein. In the second part of the book, which still contains a good deal of repetition, this non-specific form of treatment is further discussed, especially in chronic diseases such as skin affections and asthma. It is a pity that the arrangement and method of presentation of this interesting but intricate subject are not such as to minimize the inherent difficulties.

THE SINGLE-HANDED HOUSEWIFE.

MRS. MARGARET LEONORA EYLES has written a book entitled *The Woman in the Little House*.⁵ It is an account, based upon her own experiences and observations, of the manner of life of the mothers of the average working class. Mrs. Eyles has, according to the foreword written by NORAH MARCH, the editor of *National Health*, written a novel of some note, a novel with a purpose; and this book is a book with a purpose without any gilding of the pill. Her ideas of what ought to be and what is may be summed up in two passages:

“As in the old Eden legend, at the bottom of it all is the woman, the mother. Make her well, happy, comfortable, contented, whether she be queen or charwoman, and the world begins to go on smooth, oiled wheels. . . . We are not even a C3 nation to-day. There is scarcely one among us who is quite whole. The women are overburdened, the men discontented, the children born of parents not quite physically fit, brought up by parents spiritually quite unfit for their God-like duty.”

The problem is to secure the happy and contented housewife, in the little house, or in apartments, where she is single-handed, and has no helper, but must fend for herself, for her man and her children, all day and every day, in sickness and in health. That is no small problem. The writer sets out the picture in somewhat lurid colours; she has plenty of pain and a vigorous arm, and withal a somewhat irritable temper as her own confession suggests.

“For five years of my life I was never alone for one single instant; in bed, in the kitchen, shopping, gardening, always was someone very near to me, touching me most of the time. I felt sometimes as though I would come to hate these crowding people who were really so dear to me. Is it in one of these momentary spasms of impatient desire to get alone for a few minutes that murders are sometimes done?”

The house, economics, shopping and food, amusements and routine, and the sex problem are dealt with in turn. The house is all wrong, for “it was designed by men architects, and men don’t live and move and have their being in their own houses. They are more or less paying guests.” To judge from her criticisms of the houses she knew, and they are not in the slums, the local sanitary authority must have been singularly sleepy.

On the economic problem she has many things of interest to say, not least as to the married woman who goes out to work to add to the family funds.

“The home-keeping woman has no economic position. If she goes out to work the case is different. I cannot here enter into the question of the employment of mothers, except to say one thing—that the death rate among babies in Bradford is very much the highest in all England, and Bradford is the town which spends most on infant welfare outside the home; there are excellent crèches in Bradford; there are very few women who don’t go to work all day, bringing back the little ones to homes that they are too tired to clean, and scrappy meals that they are too tired to prepare after a hard day’s work in the mill.” She adds that “in looking through the archives of Dr. Barnardo’s Homes I noticed that almost every child who was sent there for being out of hand, destitute, neglected, and so on was the child of a woman who went out to work; most of the thoroughly troublesome, unmanageable little ones one encounters in the day schools are the children of mothers who have no time to be mothers.”

But difficulties are not avoided where the mother does not become an out-worker, for then “money—or the lack of it—seems to rule everything in their lives. . . . Unless they become conscienceless and drifting, or unless they get drunk and forget, they never know what it is to be free of money worry.”

She has a good word to say for the big stores and multiple shops, where food is sold of the best quality and cheaply, but for cash only. The little corner shops are snares in allowing bills to run, and dear in the poorness of the quality of their goods. The family meals are described as most unattractive. There is a “gorge” of ill-cooked food on Sundays, and a diminishing provision during the week. “The mother has

⁴ *The Evolution of Disease; with a Discussion of the Immune Reactions occurring in Infectious and Non-infectious Diseases: a Theory of Immunity, of Anaphylaxis, and of Anti-anaphylaxis.* By Professor J. Danyasz, translated by F. M. Rackemann, M.D. Philadelphia and New York: Lea and Febiger, 1921. (Demy 8vo, pp. xii + 191. 2.75 dols.)

⁵ *The Woman in the Little House.* By Margaret Leonora Eyles. With a foreword by Norah March, B.Sc. London: Grant Richards, Ltd. 1922. (Cr. 8vo, pp. 167. Price 4s. 6d. net.)

no idea of originality: she buys cheaply and badly; she knows very little about either cooking or shopping, because there is no one to teach her." The author considers the solution is to come in communal kitchens. Of amusements the working mother appears to have none—"marriage ends all the camaraderie of courtship. As soon as the first baby noars the home, the cage begins to close round the Woman in the Little House." There is nothing left but routine—monotonous, unvarying routine. The author says, "In time it will be seen that it pays to let mothers have their cooking and washing done by specialists rather than by their own amateur efforts, while they look after the children." And the State is to pay the mothers to look after the children, and there are to be convenient crèches where the mothers can leave their babies while she shops or plays. She believes that "in time there will be in every street its communal nursery." When the cooking and the washing are done for the mothers and there is a communal nursery in every street, one is inclined to wonder what the mother will find to do. Will it not be a case where "Satan finds some mischief still for idle hands to do"?

The sex problem has a separate chapter. It begins: "I shouldn't mind married life so much if it wasn't for bedtime." This remark the author avers she has heard five times. A young married woman who lamented the absence of her man at the war is told by an older woman: "No, my dear, you don't know what you're up agen yet. But you wait till you've been to bed over three thousand nights with the same man like me, and had to put up with everything. Then you'd be blooming glad the old Kayser went potty." According to the author the women "are simply bursting with a sense of injustice." Strange that we heard of no weeping and wailing and gnashing of teeth when the men came home from the war! Training in sex hygiene by pamphlets she thinks utterly futile—they "won't read pamphlets." "Sex instruction will simply have to form a part of the school curriculum, without any possibility of interference from ignorant parents; in this way the muddles that may spoil the next generation can be obviated." This statement, and the author's confession of the feeling of murder at the proximity of her dear ones, indicate the general attitude of this "reformer." The parents are "ignorant" and "interfering"; there is a cure-all by "simply" cooking for them, washing for them, nursing for them, and giving sex instruction to them. It may be that her ideas are right, but we scarcely think so. At any rate we are sure that her book will go the way of the pamphlets which she says are not read, for her writing is too much that of the chronic scold—it is wearisome.

NOTES ON BOOKS.

THE small volume *Wayside Sayings*⁶ is a collection of proverbs from many nations. The collectors say that they have preferred those which are comparatively little known, and on the whole this claim seems justified, though on the first page they do challenge the reader to catch a weasel asleep. A proverb has been said to be the wisdom of many and the wit of one; it therefore suffers in translation, but even in their English guise some of the foreign proverbs are stimulating. The publisher has his own definition, which is that "proverbs represent the inherited commonsense of a nation"; if that be true it is curious to-day to find that so many nations have a proverb about the evils which will befall a house where the hen crows. Very few proverbs with a medical reference are quoted, but "a mother's son is not her own until he has had the small-pox" is suggestive of a state of affairs in this country which has gone by. Another proverb, "drought never brought dearth to England," might, if quoted a few weeks ago, have stilled some fears. It is a pleasant book for an idle half-hour.

The *Empire Municipal Directory and Year Book*⁷ for 1922-23 is the fortieth issue of a comprehensive and convenient handbook. Besides officially corrected lists of all municipal authorities and their chief officials throughout the empire, it contains much information of general interest, including concise records of the last twelve months' progress in the several branches of municipal enterprise, sanitation, and public health. The summary of Legislation, Orders, Regulations, Memoranda, and Circulars affecting local authorities, begun in the 1918 issue, and covering the period from 1914 onwards, is brought up to date. There is also a useful bibliography of municipal and public health literature.

POST-GRADUATE EDUCATION IN LONDON.

DEPUTATION TO THE MINISTER OF HEALTH.

A DEPUTATION was received by Sir Alfred Mond at the Ministry of Health on July 13th to discuss the facilities for post-graduate education in London, especially in view of the recommendations of the report of the Athlone Committee. The deputation, which was introduced by Captain W. E. Elliot, M.P., consisted of Sir Charles Sherrington (President of the Royal Society), Sir Humphry Rolleston (President of the Royal College of Physicians), Sir Anthony Bowlby (President of the Royal College of Surgeons), Sir George Makins (President of the Fellowship of Medicine), Sir Richard Luce (Chairman of Post-Graduate Committee, British Medical Association), Sir Berkeley Moynihan (Leeds), Sir Robert Jones (Liverpool), Sir Sydney Russell-Wells (until recently Vice-Chancellor of the University of London), Dr. George Blacker (Dean of the Medical School of University College Hospital), and Mr. H. J. Paterson (one of the honorary secretaries of the Fellowship of Medicine).

SIR GEORGE MAKINS said that the problem of providing a school for post-graduate study commensurate with the opportunities offered by London for instruction in medicine had exercised the minds of teachers in London and elsewhere for many years. Among those who had taken part in the earlier stages of this movement were Sir Jonathan Hutchison, Sir William Broadbent, Sir Clifford Allbutt, and Sir William Osler. In 1918 a Fellowship of Medicine was started, at first as a social body, with a view to bringing graduates of different schools together. But it was quickly seen that it could fulfil a larger purpose, and accordingly it was amalgamated with the Post-Graduate Association, and Sir William Osler, who was president of the latter body, became the first president of the enlarged Fellowship. Since the end of 1918 some 1,300 graduates had been enrolled and had done a certain amount of post-graduate study in London. Of these students, 395 had come from civil practice in the United Kingdom, 167 from the services, 439 from the dominions, 247 from the United States, and 80 from various schools in Europe. A large number of appreciative letters had been received, acknowledging the help given by the Fellowship. The efforts of the Fellowship, however, had been hampered by insufficient financial resources. It was obvious that a post-graduate scheme of sufficient scope could not be maintained from voluntary resources alone. From the financial point of view the subject had two aspects—professional and administrative. With regard to the first, it was probable that the fees received from students would almost be sufficient to provide for the remuneration of teachers and lecturers and the cost of equipment. Administratively some capital grant was desired; such work as had hitherto been done by the Fellowship had been made possible through the generosity of the Royal Society of Medicine, which provided office and lecture rooms, and the medical journals, which freely inserted announcements. The Athlone Committee made seven specific recommendations, the seventh of which was already in process of realization, thanks to the Rockefeller gift. The Committee recognized that an existing individual school could not undertake the work of co-ordinating and regulating the numerous institutions which constituted the principal attraction of London for post-graduate students; moreover, if one school attempted to undertake these functions there might be jealousy and even opposition. For that reason the recommendation was made that a central bureau should be established, housed in a building containing not only offices, but some provision for social purposes, and that a principal officer—a medical man of standing—should be appointed to act as dean.

SIR A. MOND inquired as to the duties of this officer.

SIR GEORGE MAKINS said that it would be the task of such a dean to bring the whole of the hospitals and medical institutions into line, and to distribute people seeking post-graduate instruction among them.

SIR A. MOND said that surely a man who desired post-graduate facilities knew what he wanted. He did not undertake such study, which involved considerable expense to him, without a definite objective.

SIR GEORGE MAKINS urged that, nevertheless, the great majority of men who came from abroad or even from the provinces did not find it an easy matter in London to get the particular facilities they required.

Sir BERKELEY MOYNIHAN said that the Minister's question presupposed that a man was desirous of studying one particular thing under one particular teacher, but that was very exceptional, and he believed applied only in a very small proportion of cases. These men wanted guidance as to the lines they should follow. He agreed that if a man desired instruction in one particular branch of surgery the officer now suggested would not be necessary or would have a very limited function.

Sir GEORGE MAKINS said that the deputation laid considerable stress on the need for this dean or principal officer. On his work more than on anything else would depend the success or failure of the scheme. He agreed that in view of the present state of the public finances it might not be possible at the moment to carry out the first recommendation of the Athlone Committee relating to the establishment of the central post-graduate hospital, but he hoped that when conditions improved the University Grants Committee might be able to render aid in this connexion. He pointed out that the full development of a post-graduate scheme would have the effect of bringing together the students, at present scattered, who were undertaking post-graduate courses; it would create an academic atmosphere, and it would encourage the better use of the opportunities for research which London offered.

Dr. GEORGE BLACKER, speaking as a dean of an undergraduate medical school, said that a combination of post-graduate and undergraduate teaching was not advisable, or even feasible. Men engaged in post-graduate study did not like being taught along with undergraduates; this applied less to lectures than to clinical demonstrations and to classes conducted by question and answer. Owing to the large amount of work which had to be done in the medical curriculum, teachers of undergraduates were fully occupied, and if they were diverted to post-graduate teaching the number of undergraduates might suffer. Although there were a great number of patients in London teaching hospitals, the number suitable for teaching was not so vast as it might appear, and there was a danger, if post-graduate teaching were simply added to the other at the same place, that patients might be "over taught on." There was also considerable difficulty in providing the accommodation, many departments at present being overcrowded, and the lay authorities of hospitals could scarcely be expected to provide nursing facilities for teaching which was not a part of their own hospital schedule. It had been suggested that post-graduate teaching might be given in the units, but the proper function of the staff of the units was research and not teaching. The units could not deal with the "refresher" post-graduate who desired to rub up certain parts of his knowledge. He pleaded, therefore, for a separate institution to deal with post-graduate work.

Sir A. MOYNIHAN said that it was rather a puzzle to him where the teachers for the post-graduate work were to come from without depriving undergraduates of some facilities.

Sir GEORGE MAKINS pointed out that although the undergraduate schools might be unwilling as schools to undertake post-graduate teaching, there were always teachers in those schools who would be willing to undertake such teaching for definite periods.

Dr. BLACKER also pointed out that there were a large number of honorary consultants attached to the London medical schools who would be willing to do this work, whereas the younger teachers, actively concerned with the undergraduate work, were fully occupied.

Sir BERKELEY MOYNIHAN said that it was very desirable that post-graduate work should be organized in such a manner as to secure greatly increased efficiency. The achievements of English medicine in the past entitled them to ask for this. In medicine as in other sciences the distinguishing feature of English thought had been its originality. English thought was creative. The new idea had been born or the new vision had first been seen in English minds more often than in the minds of men of other nations. Fundamental discoveries owed their origins to England more than to any other land. In London the opportunities for post-graduate work were unsurpassed. As a student in Berlin, and as a very frequent visitor to Paris, and with some knowledge of Vienna, he could say that the resources available for clinical work in London were unrivalled, although legislation of Vienna, he could to hamper research. These resources were undeveloped, and inspiration, but with an enlightened policy and wise encouragement all these defects should disappear. Students attracted to the schools would be a great incentive to

teachers, urging them to learn and appreciate other modes of thought and widely different experience. Such a school as the Fellowship desired to see established would be a centre of intellectual traffic, a clearing house for new views, which there would be discussed, tested, and appraised. Parochialism and self-satisfaction would wither in such an atmosphere. The necessity for wide views was never more urgent than now, and the effect of visitors upon teachers would be exhilarating and inspiring. In such a centre friendships would quickly form and ripen, not only among the graduates themselves but between teachers and pupils, to the great advantage of all. Internationally this would be of the greatest value. If men of different nations laboured together in medicine they learned to understand one another; all of them sought to emulate the zeal shown by the more ardent, to value the best things, and to condone many things which at first perhaps appeared repellent, provocative, or unlovely. The social advantages of such a school would be greatly increased by the provision of a central hostel, where men could see the most of each other and have informal discussion. Students who left after a few months' work would take away something more than knowledge. They would learn the English character by seeing its variety of expression at close quarters. They would carry with them an impulse to work on English lines. The English method had its peculiarities. It sought, not so much to impose, with authority, ready-made opinions upon its students as to encourage the mind of each student to seek its own method of inquiry and expression. A student was not so much taught as encouraged to learn. Education with us was not the provision of a meal but the creation of an appetite. English methods had therefore a stimulating and germinative influence.

Sir RICHARD LUCE dealt with the special needs of the practitioners in this country in the matter of post-graduate education. The needs of general practitioners who sought instruction in general courses of medicine and surgery, as distinct from special subjects, were of two kinds. In the first place, they needed instruction directed to the revision and refreshment of their general professional knowledge, which tended to become rusty after some years of immersion in professional routine, and, in the second place, they needed instruction directed to the bringing of their knowledge up to date in those branches of general medicine in which recent advances had been made. Other general practitioners sought instruction in special subjects; they were those who, after being in practice some time, desired to take up either partially or completely some specialty in which they had become interested. The need of this class was instruction either at a special hospital or in a special department of a general hospital. That there was a genuine demand among practitioners for post-graduate education was sufficiently borne out by the evidence given before the Athlone Committee, and by the fact that courses were already being successfully carried on both in London and the provinces. Two of his own immediate neighbours, country practitioners, gave up a portion of their annual holiday year by year to go back to their old school, one to Edinburgh and the other to St. Bartholomew's, for post-graduate vacation courses. That the practitioner needed and would be benefited by post-graduate instruction was even more certain than that he was asking for it. The present demand was certainly not as great as it ought to be. Post-graduate instruction could be made available for practitioners in three principal ways: (1) by courses of instruction, theoretical and practical, at special or general hospitals where the staff was prepared to give the necessary teaching; (2) by facilities for practitioners to be attached as clinical assistants for shorter or longer periods in the special and general hospitals; (3) by lectures given by approved teachers to groups of medical men at local centres, such as those arranged by the British Medical Association. The second method was specially useful for those practitioners who required instruction in a specialty. The causes which prevented post-graduate education from being more popular with practitioners were, in the first place, lack of stimulus, the doctor getting no very direct return for his trouble, no diploma or special prestige; in the second place, expense and lack of time, for the country practitioner could not afford more than a short annual vacation, and it was only the enthusiast who would take the "busman's holiday"; and, in the third place, the fact that facilities for instruction were not brought very close to the majority of practitioners. The practitioner seeking instruction in London required the assistance of some central organization which would help him to find the class of instruction he wanted and would help

him an approved introduction to teachers. The movement for post-graduate education could best be furthered by stimulating public opinion, both medical and lay, with regard to the need of it, by providing instruction as economically as possible, and making it intellectually and socially attractive, and by ensuring that the instruction was easy of access for the practitioner. The proposal of the Athlone Committee to establish a central post graduate hospital in London was not approved by the Council of the British Medical Association.

Sir A. MOND asked the reason for this attitude of the Council.

Sir RICHARD LUCE said that he thought the Council believed that a successful hospital of the kind would be impracticable. The Council's opinion was that the movement would best be helped by the official recognition of all the institutions giving post-graduate instruction, and by the issue to them through the University Grants Committee of a share of such funds as might be available. The establishment of a central bureau in London, however, on the lines of the Fellowship of Medicine, to co-ordinate the work not only in London but throughout the country, would be a great step, and would form a centre around which the movement could grow to worthy proportions.

Sir CHARLES SHERRINGTON said that he could claim to have some personal first-hand contact with the stream of post-graduates coming from across the Atlantic. These men came to this country practically all the year round, but especially in the early summer. The Fellowship of Medicine had dealt only with a comparative few. The practitioners who sought instruction included a great many of the younger teachers at the medical schools attached to the hospitals in the United States and Canada. They were people who knew what they wanted but did not know where it was to be obtained, and it often happened that through lack of proper direction they sought it in another country—that is, a Continental country—in spite of the difference of language and of professional and nursing régime.

Sir A. MOND said that he was very much obliged to the deputation and much interested in the information placed before him. Undoubtedly the better the organization the better the results. That was quite natural in view of the rather scattered character of the London teaching hospitals. He had no doubt that it would be a good deal more difficult for people to find what they wanted in London than in Paris or Berlin or Vienna. Many people seemed to be unable to discover where London University was; with the development of the Bloomsbury scheme some of this difficulty would disappear. The problem was largely one of organization. He confessed that he had come to have a constitutional objection to the creation of more offices, and he was disposed to be critical whenever he saw the word "office" mentioned in a scheme. But he had no doubt that this particular administration could usefully be set up. The question was as to the provision of the initial expense. He would suggest that the expense should be borne by the people who were to benefit from the provision. Why should not the Americans and others who wanted information pay for it? Surely it would be possible to have an organization in which a considerable proportion, if not the whole, of the expenditure would be recovered from those who benefited. He gathered from the Athlone report that the proposed official who was to run the central office was to have the duty of arranging the whole of the courses of instruction and the management of the central hospital. He could understand that that would be a task for an experienced man, who might properly be highly recompensed. It was a different case from the one to which Sir George Makins seemed to refer, in which the function of the officer would be merely to direct to the proper source those who sought post-graduate facilities; this, surely, did not require any special ability. He knew that the members of the deputation wished to attend, as he did himself, a function at the Abbey which was due to begin almost immediately, and therefore he could not enter into a long discussion. But it was no secret that these were days of departmental economy, and that so far from being able to spend large additional sums it was a matter of considerable difficulty to obtain even small allocations. If, however, he could do anything to assist the deputation he would be very pleased, because he appreciated the importance of the case which would be laid before him. He hoped that none of them would consider the scheme of a central hospital as being in any way dead. He had been greatly impressed by the points made by Dr. Blacker, and he realized the arguments

in favour of a separate institution for post-graduate work. Some institution of this kind would be required if post-graduate work on a large scale were to be undertaken.

THE FELLOWSHIP OF MEDICINE.

The annual meeting of the Fellowship of Medicine and Post-Graduate Medical Association was held on July 14th at the house of the Royal Society of Medicine, under the presidency of Sir GEORGE MAKINS. The proceedings were very brief and formal.

Sir GEORGE MAKINS moved the adoption of the report of the honorary secretaries, which stated that 167 further enrolments of post-graduates had been made, including 22 from India and 27 from the United States. Berlin and Vienna were especially popular as centres of post-graduate study, and especially attracted a great many post-graduate students from the United States, so that the majority of the American visitors who had taken courses in connexion with the Fellowship had stayed in London only for short periods on their way to or from the Continent. The recommendations of the Athlone Committee, if carried out, would make London a world centre for post-graduate students. The establishment of a post-graduate hospital and school might for the present have to be postponed, but no time should be lost in providing a central bureau with library and hostel. This had formed the subject of a deputation to the Minister of Health on the previous day. The events of the year included the affiliation of the South-West London Post-Graduate Association with the Fellowship, the organization of special short courses in medicine and surgery, and the extension of special facilities to post-graduate students by individual hospitals, apart from the courses organized by the Fellowship itself. The medical journals were to be thanked for all that they had done to make the Fellowship known, and thanks were due also to the deans and hospital staffs who had co-operated.

After Sir W. ARBUTHNOT LANE had presented the treasurer's report, which showed a credit balance of £1,430, the reports were adopted, and the council, which consists of about 90 representatives of the individual members and 37 representatives nominated by institutions and recognized as corporate members, was elected.

The revised constitution, the result of the labours of a committee which was appointed a year ago, was approved without discussion; it defines the rules of procedure for the admission to membership and the appointment of the executive committee and subcommittees and their terms of reference. The meeting closed after passing a resolution which placed on record the indebtedness of the Fellowship to the President and Council of the Royal Society of Medicine for their continued generosity in placing rooms freely at the disposal of the Fellowship.

CONFERENCE ON BIRTH CONTROL.

A NEO-MALTHUSIAN and Birth Control Conference, stated to be the fifth international gathering of its kind, though the first to be held in London, took place from July 11th to 15th. It was organized by the Malthusian League—a body which has now changed its title to "The New Generation League for Human Welfare through Birth Control," thereby suggesting a broader platform than the old Malthusian theory. The president of the conference was Mr. C. V. Drysdale, D.Sc., and among the vice-presidents were Sir James Barr, Sir Bryan Donkin, Sir W. Arbuthnot Lane, and Sir Archdall Reid. Dr. W. J. Robinson, president of the American Society of Medical Sociology, and two or three medical men from Holland, Germany, and Sweden were also present.

The conference did its work in six sections, which discussed the domestic, economic, moral, hygienic, international, and medical aspects of the question. The fifty papers ranged over such problems as migration, organized labour, psychological factors, and the coloured races, and it was interesting to observe the way in which people who were sharply divided on other subjects found a common meeting place in birth control. The matter was pressed to the same conclusion from the point of view of the socialist and the individualist, the nationalist and the internationalist, the feminist and the one indifferent if not antagonistic to feminism, the rationalist and the minister of religion, though it should be added that, with one or two exceptions, including a New York rabbi, ministers of religion held aloof.

The Conference Dinner.

In connexion with the conference a public dinner was held to celebrate the centenary of birth control, which was dated from the publication in 1822 by the radical reformer, Francis Place, of *The Principle of Population*, a book which was said by one speaker to have been banned from the British Museum Library, but we find that this is not so. Sir W. ARBUTHNOT LANE, in a brief speech at the dinner, said that much had been heard about the neo-Malthusian theory, but the theory would be of little or no use unless women could be provided with a fool-proof method of protecting themselves against impregnation. The medical profession seemed to have no knowledge of preventives, or, where there was not complete ignorance, there was dislike of the subject, an attitude which had unfortunate results.

Professor E. W. MCBRIDE brought the good wishes of the President (Major Leonard Darwin) and the majority of the council of the Eugenics Education Society, though he said that on the executive of the body founded by Francis Galton there were sentimentalists, some of them occupying high positions in the medical world, who were opposed to birth control. He believed that eventually the State would come to adopt some form of compulsory sterilization. Professor McBride expanded his ideas in one of the sessions, when he gave an address on birth control and biological law. There would always be a residuum of people, he said, so utterly careless of the welfare of the State as to breed, regardless of consequences, and look to the State to support their children. The only remedy for such conduct was sterilization. If the practice of voluntary birth control became more widespread, then an enlightened public opinion would be formed which would support measures of compulsory sterilization against those who persisted in having families at public expense.

Medical Section.

In the Medical Section Dr. NORMAN HAIRE spoke on the sterilization of the unfit. He believed that there was little hope of cultivating public sympathy in England in favour of legislation on this subject, but many would support a campaign in favour of voluntary sterilization. Sterilization was not synonymous with castration; it involved only the interruption of the continuity of the spermatic ducts in the male or the oviducts in the female; the individual was not unsexed. The procedure had been practised in some of the American States with apparent success, and from Indiana 1,200 cases were reported. The most important indication for sterilization was disease in either parent which might seriously prejudice the offspring; another was disease in the woman which would render pregnancy dangerous or harmful. Many would be of opinion that a further indication was stupidity or carelessness leading to reckless overfecundity.

Dr. W. H. B. STODDART gave an address in the same section on some psychological aspects of the birth control problem. He said that the methods of preventing conception were three in number: abstinence, coitus interruptus, and the use of contraceptives. The use of contraceptives he believed to be harmless; abstinence was harmless in the absence of sexual stimulation; coitus interruptus was harmful. The anxiety neurosis was largely attributable to repressed sexual desire, which had been pushed into the subconscious, and there gave rise to fears which spread themselves out far beyond the original cause, and also to physical manifestations, including increased frequency of heart beat and respiration, liability to attacks of asthma and air hunger, loss of appetite, and definite malposition of the stomach, consequent indirectly upon the effect of fear on the endocrine glands, especially the increased flow of adrenaline from the suprarenal. In persons who practised coitus interruptus the stomach was commonly low down in the pelvis, causing abdominal fatigue. This applied to both sexes, but especially to the female, for the male in coitus interruptus was usually gratified. The speaker went on to refer to Professor Arthur Thomson's paper in the *BRITISH MEDICAL JOURNAL* of January 7th, in which it was suggested that the male ejaculate, through absorption by the mucous membrane of the uterus, had other effects upon the female than, possibly, to render her pregnant. It had been his (Dr. Stoddart's) custom in patients who suffered from the anxiety neurosis, due to the use of contraceptives which prevented the ejaculate from penetrating the female tissues, to give tablets of orchitis and prostatic extract by the mouth to supply the secretion which was not obtained in other ways.

Other speakers were Dr. ANTON NYSTRÖM of Sweden, who pleaded for the definite introduction of this subject into the medical curriculum, and also for a state guarantee of contraceptives; and Dr. FRANCES HUXLEY, who dealt with birth control from the standpoint of a woman gynaecologist. A resolution was passed affirming that the provision of hygienic birth control instruction should become part of the recognized

practice of the medical profession, and should be given especially at hospitals and public health centres to which the poorest classes and those suffering from hereditary disease or defects applied for relief.

The sessions of the conference were held in private, but the claims of birth control were advanced at a large public meeting presided over by Mr. H. G. WELLS, when the principal speaker was Mrs. MARGARET SANGER, president of the American Birth Control League. Mrs. Sanger gave an account of her recent visit to Japan, where, apparently, birth control ideas have found wide acceptance. In spite of the hostility of the Japanese Government, she believed she had interested large popular audiences in this subject. An organization is being established in Japan, and another in India, and one is projected in China. In some Western countries, notably France, according to Mr. Wells, the cause has suffered a positive set-back, owing to the development of nationalism. It was announced by Dr. C. KILLICK MILLARD at the same meeting that it was proposed to form in this country a medical society for the study of birth control, the main object of which would be to consider the best means of controlling conception.

In the Medical Section, of which he was president, Dr. KILLICK MILLARD reported on the replies received to a set of questions which he and Dr. Binnie Dunlop had addressed to some members of the medical profession in London and the provinces, chiefly gynaecologists. The first question was whether contraceptive methods were to be approved in the case of married couples who, on health or economic grounds, felt it necessary to limit the size of their families. To this question thirty-seven replied that such approval should be given, some of them added emphatically, while thirteen were against, and fourteen gave only a qualified approval, insisting, for example, that the couple should have had one or two children before contraceptive methods were applied, or that the grounds should be limited to health. Another question as to which contraceptive was believed to be most satisfactory elicited many diverse replies, some advocating certain pessaries and others douches, but it was worthy of note that only four voted for the cheek pessary, in spite of its advocacy in certain quarters as the best means of prevention. A third question was whether the theory was to be credited that the reduced birth rate in civilized countries was not really due to voluntary restriction by the use of contraceptives, but to retardation in natural fertility. To this question thirty-six replied that in their opinion the theory was not to be credited and eighteen that it was. The persons circularized were asked further whether they believed that chemical pessaries—such as quinine pessaries—when they failed to prevent conception might injuriously affect the resulting offspring. To this forty-six answered in the negative, three in the affirmative; of the three two gave no example in point, and the third knew of a case where such injury was alleged, but had no proof as to the cause. Dr. Millard thought that from these replies it could not be claimed that the medical profession condemned contraceptive methods, but he pleaded that the profession should awaken to this subject because, while it was silent, the solution of problems essentially delicate was being committed to laymen.

Conference at Deptford.

The results of another set of questions sent out to members of the profession and others were submitted at another conference on birth control, held during the same week at Deptford Town Hall, by Dr. C. S. THOMSON, medical officer of health for the borough. He said that he had been endeavouring to elicit the opinions of some medical officers of health and clergymen on the use of contraceptives, and whether, if their use was approved at all, they should be limited to the unfit. Six replies were received from clergymen, four of which were against the procedure. Of the eighteen replies received from medical officers, seven were in favour of birth restriction, five against, and six non-committal. Some of the medical officers considered the use of contraceptives unnatural, immoral, and physiologically wrong; others, while not objecting to their use, said that the real trouble was that they were used by the wrong people.

A NEW building for the Surgical Clinic at Munich has recently been opened under the direction of Professor Sauerbruch.

It was announced by the secretary of the Millbank Fund, at a meeting of the National Tuberculosis Association in Washington, U.S.A., that between 300,000 and 400,000 dollars of the income from the investment of 10,000,000 dollars will be set aside by the Millbank Fund to demonstrate in several districts how tuberculosis can be controlled in American communities. This demonstration has been prompted by the successful results of the tuberculosis investigation conducted for the past five years at Framlingham, Massachusetts, by the National Tuberculosis Association.

THE HOSPITALIZATION OF THE SCOTTISH ASYLUM SYSTEM.

In his presidential address given to the Medico-Psychological Association of Great Britain and Ireland at its annual meeting in Edinburgh on July 19th, Professor G. M. Robertson added another to the many appeals he has made for the conversion of the asylum with its prison stigma into the special hospital with its more human, its more sympathetic, and its more medical tone and atmosphere. A leader in these pages a couple of weeks ago* sketched in outline the various stages the proposals for reform had passed through before the draft bill to enable persons suffering from incipient mental disease to be treated in public or private mental asylums without certification was introduced into Parliament as a Government measure. It recorded the incidents in the long history of the close interest which the British Medical Association has taken in the treatment of incipient insanity; it told of the efforts of the Association's Medico-Political Committee on behalf of the care of the feeble-minded and of their success in one direction by the passing of the Mental Deficiency Act; it recalled the many bills, such as the Lunacy Acts Amendment Bill of 1905, Sir John Batty Tuke's bill for the early treatment of mental disease, the Voluntary Mental Treatment Bill of 1914, and the bill of the following year for the early treatment of mental disorder of recent origin resulting from wounds, shock, etc., which had not become Acts even when designed (as the last mentioned certainly was) to meet the exigencies of the war; and it touched more than once on the valuable lead which had been given by the experience gained in the management of the insane under the Scottish law and by the endeavours of Professor G. M. Robertson of Edinburgh. If there be any truth in the physiological and pharmacological theory of the summation of stimuli it will surely be visible in the rapid and uneventful passage of the bill now to be proposed by the Minister of Health. Whether this come to pass or not the phenomenon of the gradual hospitalization of the asylum which the President of the Medico-Psychological Association described last Wednesday has been a great historical event well worthy of record in the progress of the management of insanity.

In his introductory sentences Professor Robertson pointed out that the dominating motive which had for more than a generation directed the activities of the asylum authorities in Scotland had been the desire to make the asylum in that country an institution inspired by the same exalted principles and conducted on the same medical and nursing methods as those which existed in our great general hospitals. That ideal was simple, tangible, and high, for the voluntary hospital was the most perfect embodiment of practical humanitarianism and science, and it occupied a unique position among medical institutions. To reach the ideal meant to transform the asylum into a hospital for the treatment of a special disease. This was the meaning of the phrase "the hospitalization of the asylum" first used in 1902.

There had been difficulties in the way, and tradition in asylum management had been hard to overcome. The asylum had its origin in the prison, and neither in its construction nor in its control had it yet quite got free of its origin. The single rooms of the asylum took one's thoughts back to the cells, and so did the practice of confining patients in them. The exclusion of women and their non-employment in nursing the sick and the infirm in the male wards of asylums was another result of the past; it was a perpetual reminder that the original conception of an asylum was less that of a hospital for the care and treatment of a special disease than that of a safe place of detention for the custody of a dangerous class. The public had found mental patients unfit to be at large; it had officially through a judge or magistrate deprived them of their liberty; it had ordered their detention in special institutions primarily for the purpose of safety; it had, of course, expected them to be cared for kindly, but it had scarcely realized how difficult the task was, forgetting that the deprivation of liberty itself was a hardship. The public, therefore, had swung to and fro between sympathy for persons "illegally detained or harshly

treated," and indignation that insane and dangerous people were not more stringently shut up.

"As liberty is the most cherished prerogative of the human being, it is not without good reason that persons of unsound mind are deprived of it. The measure is required for their care very often involve questions of life and death. Every melancholic patient at one stage or another of his illness is a case of potential suicide; every patient suffering from hallucinations of hearing and from delusions of persecution is a possible homicide; while the weak-minded and the impulsive are all liable to commit irresponsible acts of a dangerous character. Were such patients treated with a sole regard to their wishes and feelings, tragedies would happen which would move the public to indignation. It has in a large measure escaped such experiences, and in consequence it seems probable that a section of it does not realize that any danger exists at all. The medical superintendent of an asylum is a man who walks on the edge of a precipice, who lives over a powder magazine, and he is wise to err on the side of safety."

In Scotland the medical superintendent was the sole authority over all that related to the medical care of the patients, and he alone admitted or discharged them. Quite properly he was controlled by a board of able men, and, naturally, expense had to be considered at every step, a fact which checked and limited extreme medical and philanthropic aspirations. It would be immensely for the benefit of patients in rate-aided asylums if the number of the staff were doubled; but public authorities would not submit to the extra expenditure. Many difficulties had to be overcome before reforms could be instituted, and prejudice against innovation was a recognized barrier; but the General Board of Control (the Government Department controlling the application of the lunacy laws) had done well in encouraging advances by refusing to stercotype an official system of treatment or of asylum construction. The Board had given freedom of initiative and scope for individual action to medical superintendents in Scotland, and many of them had struck out new lines in such directions as the amusement of the patients, their degree of freedom, the nursing of them, the clinical or laboratory investigation of their maladies, and the like; the Board had made known advances in one asylum to the workers in others.

The great and outstanding result of the innovations introduced by medical superintendents in various places had been the gradual abolition of the prison features of Scottish asylums. Professor Robertson's description of the order and manner of the changes which marked the transition from prison-like asylum to modern hospital for mental diseases was masterly. Soon after 1857 it was thought that the attachment of "airing courts" to asylums marked a noteworthy advance in asylum construction; so in a sense it did, but it was really a feature inherited from the prison, and therefore it had to be replaced by permitting the patients to walk freely about in the grounds round the institution, an advance due to the initiative of a single superintendent. Mechanical restraint by various means (strait-jackets, hobbles, muffs) was obviously the prison tradition again.

Then came the era of "non-restraint," for which all honour is due to Gardiner-Hill and Conolly; but they modified rather than abolished restraint, for Conolly invented the padded room—defined as "a room of which the floor is a bed and the four walls are padded"—and he used confinement in single rooms, euphemistically termed "seclusion." These improvements came in their turn to be abused, and about twenty years ago statistics of their employment in different asylums were published, and very soon, in Scotland, seclusion and padded rooms began to disappear generally. Another relic of the prison idea was the locking up of troublesome patients at night and the lack of any nocturnal treatment of mental symptoms even in convalescent cases; gradually the substitution of continuous personal attention for the mechanical safeguard of a locked and shuttered room was introduced, and instead of one night-watchman for both male and female sides of an institution a night staff sufficiently large for the efficient care of all patients who might require it was introduced. The locked doors of the asylums of the past increased the prison atmosphere: Sir John Tuke observed that in an asylum suitably constructed this unpleasant feature could be almost eliminated, and so the "open-door system" came into being, was extended to the use of detached villas without obvious institutional characters, and finally took the form of permission to go about freely on parole. The "boarding-out system" in country districts marked a further departure from the prison idea, and at the present time over 2,000 unrecovered but harmless patients were being so cared for in Scotland. "Here," said Professor Robertson, "our practice has gone as far away as it possibly could from any suggestion

* BRITISH MEDICAL JOURNAL, July 8th, 1922, p. 51.

of prison or restraint, and the unrocovered patient is replaced in a natural home under more familial and domestic supervision."

Professor Robertson passed next to the consideration of the introduction of hospital features into the asylum set free from its prison-like characters. In this matter the late Sir Thomas Clouston was a distinguished pioneer in Scotland. He taught that an asylum should be an institution for medical observation and treatment, and to enforce this idea his favourite recommendation was that every asylum should be provided with a separate hospital block; this would bring with it a medical atmosphere. At the present time the majority of modern Scottish asylums were provided with these separate and distinctive hospitals. Another advance towards the hospital idea was made by Dr. Campbell Clark in 1880 when he began courses of instruction for nurses and attendants, and published his *Handbook for Attendants on the Insane*; next came the Medico-Psychological Association's certificate of proficiency in mental nursing. "Thus," said Professor Robertson, "thirty years before the recent Act for the registration of nurses was passed, mental nurses through the agency of this association enjoyed practically all the advantages now being conferred for the first time on hospital and other nurses."

The next great movement towards the hospital idea was the bringing of women prominently into the staffing of the asylum. The appointment of hospital nurses as matrons of the female divisions of asylums not only improved the quality of the sick nursing, but also placed educated women with medical training and instincts at the head of the female staffs. "At first these women had not the special knowledge necessary for the safe and proper care of the insane; but by the appointment of three hospital nurses as assistant matrons and their training in mental nursing and asylum management proper candidates for the matronship in Scotland were soon forthcoming. Matrons and assistant matrons who were possessed of hospital training quickly brought about the replacement of asylum methods by hospital ones equally good or better, and many features alien to hospitals thus disappeared. Then the change began to affect the male wards of the asylum; women with their "mothering" instincts began to find their way into the male portion of the institution, first as wives of charge attendants as "auxiliary female care," then in complete nursing charge during the day, then during the night (with auxiliary male care when it was necessary), and finally as matrons over a whole asylum (male and female sides), whereby "the analogy to the general hospital was rendered more complete." Professor Robertson's remark is: "A woman continues to exercise much the same subtle influence over an insane man who is not actually delirious and confused as she does over one who is supposed to be in his right mind." One scents a trace of humour here.

The approximation to the hospital idea was seen also in the increase in the numbers of the medical staff and in the more thorough study of the physical disorders associated with insanity by all the scientific methods of investigation in use elsewhere. Higher education in the science of psychiatry and the giving of diplomas in psychological medicine were other signs of approach to the hospital character. Curiously enough the State had taken little or no interest in the last-named advance in the treatment of insanity, although everything which makes for more successful treatment and for more effective prevention of insanity will save the State money. "One mental disorder alone—namely, dementia

the country more in maintaining its
if than any other single disease."

was needed in respect of the laws

under which Scottish asylums were administered. The law was archaic: it was designed to suit a form of social life which no longer existed and which medical science and the art of nursing had left far behind. Professor Robertson's words on this matter were weighty:

"As the Board of Control has admitted the necessity for a new Act, let us hope that it will be framed on medical lines, and particularly that under its provisions it will be possible for any unfortunate person who is sick in mind to obtain the medical treatment and nursing his illness requires, without first being legally branded a lunatic, as at present, and then committed to detention by a judge or magistrate, as if he were a species of criminal. After all, such a procedure is not very different from the trial of the sick person in Samuel Butler's *Erechon*, who, suspected of being consumptive, was apprehended and tried as a common criminal would be with us for burglary. Not till the cruel anachronism of these laws is removed, which after sixty-four years' service have outlived their purpose, will the asylum shed

its last prison features, be cleansed of the prison taint, and be free to develop along purely medical and hospital lines. That it can be removed without evil consequences following is demonstrated by the amazing situation that has come to pass in Scotland, where the majority of private patients paying the higher rates of board are actually being admitted to the Royal asylums, not under medical certificates and judicial orders, as was intended by our well-meaning legislators of other days, but as voluntary patients. Why should it not be possible for the rate-aided poor to enjoy this privilege? Their need is just as great as those endowed with wealth, and, being without means, they are less likely to be the victims of designing persons or plots. But, as a matter of actual fact, no one, rich or poor, has ever been found by our courts of law to have been wrongly detained in a Scottish asylum."

Professor Robertson concluded his address by pointing out that the essential features in the changes in the asylum system of Scotland during the last two generations could be crystallized into two simple yet comprehensive ideas or formulae. These were, first, the abolition of prison features, which were an inheritance from the past, by the substitution of continuous personal attention; and secondly, the hospitalization of the asylum by the introduction, as completely as possible, of the methods employed in hospitals for investigating, treating, and nursing disease, which still remains the ideal for the future. A revolution had actually occurred, but it had come so gradually that it had had none of the inconveniences associated therewith; indeed, so quietly had it come and so insinuatingly that many were putting forward the query, "Had the type of insanity changed to one of milder symptoms?" Where were the raging maniacs of the past? The answer had unfortunately to be that their raging had been in some measure the result of the treatment accorded to them.

Professor Robertson did not close on the note of prevention, but it could be detected, if listened for, in every part of his address. How much better it would be for everyone if all cases of non-congenital insanity could be treated in the incipient stage; how much more economic in every sense for the country. Even congenital mental disorders may prove amenable to prevention, but in their case prevention must begin with the parents and be ante-natal in time. This address is an additional and a potent argument in favour of the long looked for Incipient Insanity Bill.

TRANS-ATLANTIC RHINO-LARYNGOLOGY.

PROFESSOR BIRKETT'S SEMON LECTURE.

THE Semon Lecture, under the auspices of the University of London, was delivered on July 12th by Professor H. S. BIRKETT, C.B., M.D. (Dean of the Faculty of Medicine of McGill University, Montreal), who took for his subject "The development of trans Atlantic rhino-laryngology." The Vice-Chancellor of the University (Mr. H. J. Waring, F.R.C.S.) presided.

Professor BIRKETT began with a personal tribute to the man in whose memory the lecture was founded. It was now more than thirty years ago since he first met Sir Felix Semon, and during many visits to this side of the Atlantic the acquaintance ripened into friendship. Semon jealously guarded and strenuously upheld the dignity of the specialty to which he devoted his life. He was frank and decided in his opinions, and as an investigator in the field of laryngology and a contributor to its literature he stood pre-eminent.

The close ties existing between the English-speaking countries made it desirable that each should know more of the work done by the others, in this as in other directions. To the United States belonged no small share in the discovery and development of the fundamental principles which had placed laryngology in the foremost rank of specialties. Both the origin of the specialty and the conception and development of its important principles had been the product of the splendid speculative and inventive genius of America. He quoted Sir William Milligan as having stated that to their American colleagues past and present much credit was due, not only for pioneer work, but also for the persistent way in which they had kept the laryngological flag flying.

The lecturer then went on to instance the earliest papers appearing in medical publications in the United States on the subject of laryngology, dating from 1860 or thereabouts. The man who was entitled to be regarded as the father of American laryngology was Horace Green, who, at the time (about 1852) when the laryngoscope was regarded with more or less scepticism, foresaw its possibilities, and stated that he was confident that if the instrument could be brought into

general use the profession would be able to cure diseases which up to then had been frequently overlooked. Green had graduated in medicine in 1834, and he was the first medical man on the American continent to devote himself exclusively to diseases of the respiratory tract. In 1846 he published a treatise on diseases of the air passages. The name of Louis Elsberg must be associated with that of Horace Green. Elsberg was described as the most accomplished laryngologist in America, and he became the first president of the American Laryngological Association. The earliest classical textbook on the subject of foreign bodies in the air passages was by Samuel D. Gross, and was published in 1854 in Philadelphia. With the more general use of the laryngoscope the literature on the subject enlarged rapidly. In 1864 Elsberg brought out a little monograph on *Laryngoscopic Medication*, which was the first trans-Atlantic work on mirror laryngology. At that time Elsberg was lecturer on diseases of the larynx in the University of New York. For comprehensiveness and originality the treatises of J. Solis Cohen (from 1872 onwards) had not been beaten in American laryngological annals.

The first laryngological society was founded in New York in 1873. It was "A Society for the Study of Affections of the Larynx, Pharynx, and Adjacent Parts," and was merged later into the Section of Laryngology of the New York Academy of Medicine. Afterwards, under the presidency of Louis Elsberg, the American Laryngological Association was formed. As for instruction in laryngology, the first official teaching was inaugurated in Philadelphia (by J. Solis Cohen) and at Harvard, in both cases about 1866; but Elsberg, in the autumn of 1861, had started lecturing on laryngology in the medical department of the City of New York University, and this was the first regular instruction given in America. The Metropolitan Throat Hospital in New York was established in 1874. In 1875 the Harvard Medical School included laryngology as a separate subject in its curriculum. The first journal dealing with the subject was the *Archives of Laryngology* in 1880, but only four volumes were published. The photography of the larynx was successfully accomplished by French in 1882—a triumph of ingenuity, skill, and persistence. Another epoch-making advance was the introduction of Joseph O'Dwyer's intubation method in New York in 1885; and to Fletcher Ingals, Chevalier Jackson, and others much credit was due for work on bronchoscopy. Ingals was the first to make use of the distant method of illumination, and Jackson perfected this method.

Passing to rhinology, the lecturer said that the development of this subject was more gradual than the other, and it was only through the large number of contributions to literature by American workers that encouraging advance was at length obtained. An important piece of study was the removal of intranasal obstructions; the first to carry out this removal was J. Solis Cohen. W. H. Day was the first to call attention (in 1882) to the connexion between hay fever and nasal diseases. J. N. MacKenzie drew attention to the fact that in the nose there was a well-defined sensory area capable of producing an excitation which found expression in a series of reflex phenomena. The lecturer instanced other advances which had come from across the Atlantic, notably the discovery by W. H. Betts of New York, in 1896, of the value of extract of the suprarenal capsules as a haemostatic—a useful adjunct in controlling bleeding in nasal operations.

As for undergraduate teaching in America, the subjects of laryngology and rhinology had been for some years past compulsory in the curriculum of most of the leading American universities. Instruction was given for one year, and an examination in this subject, written and oral, was held. Licensing bodies required an examination in these special subjects. Post-graduate teaching was first introduced in New York in 1877, and was gradually advanced until at the present time some of the chief medical centres had their own post-graduate institutions, in which excellent facilities were afforded for this special line of work. It was realized by Elsberg as far back as the seventies that the education of the specialist would require years of study, and a committee which was appointed to consider the matter made certain recommendations, which were adopted by the societies interested in the subject. The principal recommendation was that the student must have a minimum training of eighteen months in full-time work on this special subject, one-half of the day to be devoted to the clinical study of cases in a well-equipped out-patient department of a general or special hospital, and the other half to the fundamental sciences and allied work,

carried on in equally well-equipped laboratories. The early custom on the other side of the Atlantic was to unite otology with ophthalmology, and with the development of rhinology all three specialties were in many instances combined. In the late seventies an attempt was made to dissociate rhinology and otology from ophthalmology, and for the past twenty years, in most of the medical schools, these subjects were associated with laryngology in one chair. On looking back over the broad outline one could not but be impressed by the immense strides which had been taken, more particularly during quite recent years. Once the avenues of research were opened, the work and experience of one observer after another formed an arch through which gleaned ever-widening fields for investigation.

A vote of thanks to the lecturer was proposed by Sir J. DUNDAS GRANT, who said that American laryngologists had set a stimulating example. He also paid a tribute to Semon, who, he said, was one of the greatest of teachers—encouraging, stimulating, and often disturbing, through the activity to which he called his colleagues and pupils. Sir ST. CLAIR THOMSON, in seconding the vote of thanks, appreciated the lecturer's backward view. Those who looked forward saw only one way of advance; those who looked backward saw more than one. The vote of thanks was heartily accorded, and the Vice-Chancellor then handed Professor Birkett the Semon medal.

THE ROYAL ARMY MEDICAL CORPS.

UNVEILING OF THE MEMORIAL TABLET.

The tablet placed in the nave of Westminster Abbey in memory of the officers and warrant officers, non-commissioned officers, and men of the Royal Army Medical Corps who fell in the great war was unveiled with simple ceremony by the Duke of CONNAUGHT, colonel-in-chief of the Corps, at noon on July 13th. The congregation which filled the nave included Princess Christian, and many representatives of the Government, the army, and the medical profession. The large number of ladies present were, in almost all instances, relatives of those who had died.

The tablet, an illustration and brief description of which appeared in our last number, is on the north wall, just beneath some large and tasteless memorials of eighteenth-century valour. It strikes a quieter note, in harmony with the tomb of the "Unknown Warrior" a few yards distant, and yet it arrests the eye, like the widow recently dedicated to the fallen of the Royal Flying Corps, which is almost opposite.

The service under the grey arches was all the more impressive because there was no sermon or address; the occasion was allowed to speak for itself. The majority of those present wore either military uniform or academic robes, and these, with the white surplices and red cassocks of the choir, made a spectacle of colour not often seen even in the Abbey. The assembly in such a setting of so many men of distinction in arms and in medicine might well have formed the subject of an historical canvas. The music was provided by the band of the Welsh Guards, which before the service began rendered selections from Grieg, Sullivan, and Bizet, and also accompanied the hymns with which the service opened and closed; these were Charles Wesley's "Jesu, lover of my soul," the first verse omitted, sung to the tune "Aberystwith," and Bishop Walsham How's "For all the saints who from their labours rest," to the tune "Sine nomine." A word of praise is due to the party of buglers who, at the end of the ceremony, from behind the high altar, sounded "The Last Post" and "Réveillé." Those piercing notes must have brought to many present the most emotional moment of the service.

A guard of honour of the R.A.M.C. was posted outside the west door, and was inspected by the Duke of Connaught on his arrival. On entering the Abbey His Royal Highness was received by the Dean (Bishop Ryle) and the clergy and conducted to a seat in front of the tablet. After some opening prayers by the preacher the "Contation of the Faithful Departed" was sung, and then the Duke, removing from the tablet the Union Jack which had covered it, said:

I have the honour to unveil the tablet erected in Westminster Abbey by the Royal Army Medical Corps in memory of the 743 officers and 6,130 warrant officers, non-commissioned officers, and men of the corps who fell in the Great War; and at the same time to announce that in due course the names of those who fell will be engrossed in a Golden Book, now being prepared, that will be kept

among the treasures of the Abbey in the Chapter House. The Royal Army Medical Corps has generously assigned the sum of £10,000 to the fund for the restoration and maintenance of the structure of Westminster Abbey.

The DEAN dedicated the tablet in the following words:

To the glory of God and in the name of Jesus Christ, we dedicate this memorial in proud and thankful memory of those officers and men of the Royal Army Medical Corps who fell in the Great War; in the name of the Father, and of the Son, and of the Holy Ghost.

The DEAN added:

On behalf of the Dean and Chapter of Westminster Abbey we desire to express our gratitude for the great and magnificent donation of £10,000 by the R.A.M.C. to the Westminster Abbey Restoration Fund, and it will be our pride and pleasure, in time to come, with the proper consents, to preserve in the Chapter House the great Golden Book among the treasures of Westminster Abbey.

Following the dedication a special collect was said:

O Almighty Father, Lord of heaven and earth: Vouchsafe, we beseech Thee, to accept this offering at our hands for the adornment of Thy house of prayer, and in thankful memory of our brethren of the Royal Army Medical Corps who fell in the Great War; and grant that as we dedicate this gift to Thy glory, so we may devote our lives to Thy service, for Jesus Christ's sake. Amen.

This was followed by a sixteenth-century prayer:

O Lord, support us all the day long of this troublous life, until the shades lengthen, and the evening comes, and the busy world is hushed, the fever of life is over, and our work done. Then, Lord, in Thy mercy, grant us safe lodging, a holy rest, and peace at the last, through Jesus Christ our Lord. Amen.

After the National Anthem the Duke of Connaught and Princess Christian proceeded to the Chapter House to inspect that part of the Golden Book which has already been prepared. The execution of this work has been entrusted to Mr. Graily Hewitt, one of the most talented scribes of the day. The book will consist of between two hundred and three hundred pages, each of them richly illuminated and bearing a different design, and the whole will be elaborately bound. The work is expected to take eighteen months to complete.

The Duke of Connaught was accompanied from the west door to the site of the tablet, and again, after the service, to the Chapter House, by Lieut.-General Sir John Goodwin (Director-General of the Army Medical Service), Lieut.-General Sir G. M. W. Macdonough (General Sir Arthur Keogh, G.C.B.), Lieut.-General Sir W. Laurence Gubbins (General Sir Arthur Sloggett (late officers of the Service).

Amongst those present in the congregation were Sir A. Mond, Field-Marshal Lord Methuen, the Right Hon. F. E. Guest (Secretary of State and President of the Air Council), Vice-Admiral Sir Robert Hill (Director-General, Medical Department, R.N.), Lieut.-General Sir Travers Clarke (Quartermaster-General to the Forces), Lieut.-General Sir William Peyton (Military Secretary to the Secretary of State for War), Major-General G. D. Jeffreys (Commanding London District), Sir Herbert Creedy (Secretary of War Office and Army Council), Sir Charles Harris (Permanent Head of the Finance Department of War Office), Bishop Taylor Smith (Chaplain-General), Major-General Sir R. Havelock Charles (Medical Adviser to the Secretary of State), General Sir A. P. Blenkiron (D.D.M.S. E), Lionel Earle (representing the First Comm), MacAlister (President of the General Medical Council and Vice-Chancellor of the University of Glasgow), Mr. H. J. Waring (Vice-Chancellor of the University of London), Dr. J. G. Adams (Vice-Chancellor of the University of), (President of the Royal College of), Bowly (President of the Royal), Sir David Wallace (President, burgh), Sir W. Wheeler (President, Royal College of Surgeons in Ireland), Sir George Makins (President, Fellowship of Medicine), Mr. James Barry (President, Medical Society of London), Sir Archibald Garrod (Regius Professor of Medicine, University of Oxford), Lord Dawson of Penn, Sir Berkeley Mynihan, Bt., Sir Charles Ballance, Dr. Andrew Balfour, C.B., Dr. W. P. R. Burgess (Master, Society of Apothecaries), Sir John MacAlister (Royal Society of Medicine), Professor Ivyle Cummins (Welsh National University Medical School), Sir Charters Symonds, Sir L'Arcy Power, Sir Robert Jones, Sir John Lynn-Thomas, Sir James Galloway, Mr. Warren Low, C.B.

The British Medical Association was represented by Professor David Drummond (President), Dr. R. A. Bolam (Chairman of Council), Dr. Wallace Henry (Chairman of Representative Meetings), Dr. G. E. Haslip (Treasurer), Major-General Sir Richard Luce, Rear Admiral Sir Percy Bassett-Smith, Dr. T. Ridley Bailey, Dr. J. W. Bone, Dr. H. B. Brackenbury, Mr. W. McAdam Eccles, Lieut.-Colonel R. H. Elliot, Dr. A. C. (Editor, BRITISH MEDICAL JOURNAL), Dr. N. (Editor), Dr. Alfred Cox, O.B.E. (Medical Secretary), and Dr. A. Courtenay Lord and Dr. A. D. Macpherson (Assistant Medical Secretaries).

Among the army medical officers present in addition to those mentioned above were: Major-General Sir G. B. Stanistreet

(Deputy Director-General), Major-General Sir William B. Leishman, Major-General Sir W. G. Macpherson, Major-General Sir Hayward R. Whitehead, Major-General C. E. Pollock, Major-General Sir W. Russell (late Deputy Director-General), Major-General Sir G. D. Bourke.

Representatives of the Red Cross Society and the Order of St. John were present; also the matrons-in-chief of the Queen Alexandra Nursing Service and the Territorial Nursing Service, and Colonel C. R. Tyrrell, C.B., and Major E. B. Waggett, D.S.O. (joint secretaries of the Memorial Committee).

All the medical faculties of universities in the United Kingdom not actually represented in the Abbey sent letters of regret, stating that the reason for inability to send a representative was that vacation had already commenced.

THE CAUSE OF INFLUENZA.

As influenza is among the foremost of the epidemic diseases that periodically ravage humanity, any further light upon its etiology is welcome, and the report to the Medical Research Council by Professor James McIntosh of his careful researches during the later stages of the pandemic of 1918-19 will be read with much interest and no little profit by a large circle of readers.

Professor McIntosh's object was to define the cause of influenza, and he outlines, in the first place, the conditions that must be fulfilled before a virus can be accepted as the cause of a disease, and refers to Koch's postulates. He points out, however, that in the case of influenza many difficulties arise in arriving at a correct conclusion. These are due in part to the present lack of clinical means of sharply differentiating influenza, but in part also to the difficulty of being sure that clinical changes and pathological lesions produced experimentally in animals constitute true influenza.

In illustration of the former point he remarks that when influenza first appeared among our troops in France in the spring of 1918 it was not at once recognized either by clinicians or by bacteriologists, and was put into the category of P.U.O.—pyrexia of uncertain, not of unknown, origin as stated.

Bacteriology.

The methods used by Professor McIntosh in the investigation described in his report consisted first of examining films of exudates—chiefly of sputum and serum and using fuchsin or neutral red stain. From the information in this way a preliminary diagnosis was obtained. In the majority of cases, he employed for culture either Matthews's trypticized blood agar, boiled blood agar, serum agar, or ordinary agar. For preserving *B. influenzae* alive he employed boiled blood agar, and he gives exact particulars of its preparation. His results are summarized in a series of tables. When controls and cases not characteristic of the outbreak were excluded, he found the percentage incidence of various micro-organisms in forty-eight cases examined in the acute stage of influenza to be as follows:

<i>B. influenzae</i>	75 per cent.
Streptococci	33.3
Pneumococci	27.0
Gram-negative cocci	27.0
Staphylococci	22.2

The bacillus of Pfeiffer was also found in the nasopharyngeal secretion of 13 out of 17 cases of early acute, uncomplicated influenza, in the sputum of 58 out of 70 cases of influenzal bronchopneumonia, and in 36 out of 48 cases examined after death from influenza. In a special series of 16 cases examined post mortem Pfeiffer's bacillus was found 15 times. In the pus of 12 empyemata it was detected twice.

Serological observations were found to furnish additional evidence of the close association between Pfeiffer's bacillus and influenza, since no less than 12 out of 19 unselected convalescents were found to give positive complement fixation with *B. influenzae*; and out of 22 similar serums tested for agglutinin to *B. influenzae* 8 gave positive results in dilutions up to 1 in 100.

It is important to note that serum of influenza convalescents when administered to acute cases in doses of 10 to 30 c.cu. was found to benefit the patients very considerably, and a number of temperature charts are given to illustrate this good effect. It is pointed out, however, that claims have been made that normal serum can produce a similar result, and Professor McIntosh refrains from expressing an opinion as to the mechanism of this therapeutic action.

Morbid Anatomy and Histology.

The morbid anatomy and histopathology of influenza is briefly reviewed and the statement made that epidemic influenza is essentially an acute inflammation of the respiratory tract with involvement of the lungs, the most striking

feature being a marked engorgement of the trachea and bronchi and a general congestion and oedema of the lungs. In sections bacteria were usually to be found in large numbers in the mucous exudate, on the surface of the mucosa, among the epithelial cells, or in the submucous exudate. In many instances only small Gram-negative bacilli (*B. influenzae*) were to be seen. In others numbers of different cocci were to be found, mostly in association with *B. influenzae*. In the lymphatics of the bronchi *B. influenzae* could be found either alone or associated with pneumococci or streptococci. It is noteworthy that the earliest changes in the lungs were found to be a dilatation of the capillaries and a pouring out of clear-albuminous fluid, which in places completely filled the alveoli; apart from red corpuscles, cellular elements and bacteria of any kind were rare in this alveolar exudate at the early stage, though bacteria were present in the bronchi. These results agree with those of previous observers.

Pathological Experiments.

Having demonstrated the close association of *B. influenzae* with the disease in the manner described, Professor McIntosh attempted to produce influenza experimentally, and here, as might have been anticipated from his opening remarks, the chief difficulty was encountered. A study of the pathogenicity of *B. influenzae* for laboratory animals showed that this organism was fatal to mice when administered intraperitoneally in doses of 1 to 4 milligrams of a young culture. He then investigated the production of a soluble toxin by *B. influenzae*, and confirmed the observations of Julia Parker and others that a soluble toxin can be demonstrated in young cultures of this organism. The toxicity of filtered cultures to rabbits varied considerably, but as a rule 5 to 6 c.cm. of the filtrate was sufficient to make the animal seriously ill. In the case of guinea-pigs the average lethal dose was 2 to 3 c.cm., but with some batches of toxin the lethal dose was 0.5 c.cm. or less. Perhaps the most suggestive train of symptoms were those produced in an animal when death occurred in four or five hours. Immediately after injection the animal became collapsed, its fur ruffled, and its temperature subnormal. Some time later a discharge of frothy mucus was observed at the nose, and there was slight diarrhoea. *Post mortem* the lung lesions in rabbits and guinea-pigs were so constant that the toxin, it is thought, may be assumed to have a definite selective action on the respiratory mucous membrane. The lesions produced by the toxin were found to bear a close resemblance to those present in man when an attack of influenza causes death.

In discussing the nature of the soluble toxin formed by *B. influenzae*, Professor McIntosh expresses the opinion that its action is distinct from that of protein degradation substances produced by the growth of bacteria in the medium, and in support of this view he adduces the circumstance that the toxin is thermostable, and also that it produces in animals such definite histological changes. Further, he looks on the fact that it excites the production of specific antitoxin as convincing evidence on this point. It is interesting to note, however, that normal rabbit serum has some neutralizing action on the toxin, and further that it has not yet been found possible to neutralize multiple doses of the toxin with the antitoxin. It is possible that the toxin is a mixture, and Professor McIntosh is hopeful about further developments in this relation.

Having defined in this way the intimate association of Pfeiffer's bacillus with influenza, and the capacity of its toxin to reproduce experimentally the chief lesions found *post mortem* in that disease, Professor McIntosh endeavoured to produce influenza experimentally in monkeys, rabbits, and guinea-pigs. He used both filtered and unfiltered material from cases. The former series included both nasal and post-nasal secretion, blood, and freshly isolated pathogenic cultures of *B. influenzae*, and the filtered material comprised the filtrates of nasal washings, throat washings, and lung juice. The results were quite negative, with the exception of a doubtful result produced in a monkey by intratracheal insufflation with a culture of *B. influenzae*.

Dr. McIntosh sums up the results of this investigation in the following conclusions:

Conclusions.

1. The predominating micro-organism in the secretions and lesions of the late epidemic was *B. influenzae* (Pfeiffer), which could be demonstrated in over 80 per cent. of the cases.
2. Other members of the catarrhal group of bacteria (pneumococci, streptococci, Gram-negative bacteria, etc.) were much less frequent.

3. Serological examinations, in particular the complement fixation test, confirmed an infection by *B. influenzae*.

4. Epidemic influenza, as shown by the pathological lesions, is essentially an acute inflammation of the respiratory tract.

5. In the early stages the lung changes are more suggestive of a toxic action than bacterial. In the later stages the lung picture may be complicated by other microbial infections.

6. The therapeutic effect of injections of the pooled serums of influenzal convalescents, even in severe cases, was very encouraging.

7. *B. influenzae* is a pathogenic microbe, producing its main lethal effect by means of a soluble toxin.

8. The experimental inoculation of animals with filtered cultures of *B. influenzae* produced pathological changes which presented a close resemblance to the changes found in man.

9. Injections of *B. influenzae* vaccine can produce in susceptible individuals a typical influenzal attack of short duration.

10. No evidence was obtained in support of the view that influenza is due to a filter-passing virus.

Interpretation.

Professor McIntosh criticizes severely the evidence that has been brought forward in support of the view that a filter-passing organism is concerned in the causation of influenza, and he does not seem to reject it *in toto*. He also contends that the minute bodies observed in cultures of filtered material derived from influenza cases have not been differentiated with certainty from inanimate particles present in all albuminous fluids. His survey of the literature, however, does not include the whole of the evidence; we do not, in particular, find an account of the recent work of Olsky and Gates of the Rockefeller Institute, to which reference has been made in our columns (September 17th, 1921, p. 455).

While Professor McIntosh has demonstrated in a very convincing manner the important part played by Pfeiffer's bacillus, and thrown much light on the mode of its pathogenic action, he has not yet succeeded experimentally in producing with certainty influenza. This circumstance, and the admitted frequency of Pfeiffer's bacillus in conditions other than influenza, are difficulties that will cause many to hesitate before accepting Professor McIntosh's able and earnest plea for regarding the bacillus of Pfeiffer as the primary and essential cause of epidemic influenza. It is to be hoped that the forthcoming discussion on the bacteriology of influenza at the Glasgow meeting of the British Medical Association will throw further light upon this important subject.

ROYAL MEDICAL BENEVOLENT FUND.

A MEETING of the Committee was held on June 15th; 40 cases were considered and £540 granted to 38 applicants. The following is a summary of some of the cases relieved:

M.R.C.S. Egan, aged 60. Owing to an accident to the knee he had been out of employment since leaving ship service, and appealed to the Fund to help him to get back to Australia. Voted £3 towards passage money.

Daughter, aged 61, of M.D. St. Andrews who died when applicant was a child. She is a trained nurse and served through the Boer war, after which she opened a nursing home in South Africa, but had to give this up, and then took up private nursing. Came to England in 1914, and was refused by the War Office on account of age. Afterwards served abroad with various Red Cross units during the war. She now has £15 a week from the United Service Fund, and a little help from friends. Voted £0 in twelve instalments.

Widow, aged 57, of M.B.E. Lin, who died suddenly in 1918. Applicant has been living on her late husband's life insurance money and the proceeds from sale of furniture. She tried to make a living by letting the rooms in her house, which is heavily mortgaged, but owing to ill health had to give this up. Applicant has gone back to her native place and is living in a cottage. Voted £5.

Widow, aged 94, of medical man who died in 1887. She is now confined to her house. She has only the old-age pension, and her rent amounts to 6s. a week. Voted £25 in twelve instalments.

Applicant, aged 55, of L.R.C.P. and S. Edin. who died in December last. Applicant lives with married daughter, who only has £2 a week. Her late husband was a pensioner on the Fund at £26 a year. Voted £5.

Subscriptions may be sent to the Honorary Treasurer, Sir Charles J. Symonds, K.B.E., C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1. The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessities, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for secondhand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

THE new building for the medical school at Porto Alegre, Brazil, is approaching completion, and classes will probably be held during the coming year in the building; the staff includes some forty professors and assistants.

British Medical Journal.

SATURDAY, JULY 22ND, 1922.

THE HOSPITALIZATION OF ASYLUMS.

In a leading article published on July 8th (p. 51) it was pointed out that medical opinion is unanimous that the present lunacy laws are urgently in need of reform, and, in view of the fact that legislation to give facilities for the treatment of early cases of insanity will shortly come before Parliament, we do not hesitate to emphasize again the necessity for the removal of certain restrictions which at present constitute a barrier to the adequate treatment of mental disorder in its incipient stages. It must be remembered that the impetus towards reform did not originate from the general public; it originated from the psychiatrists themselves, who have been fully alive for a number of years to the limitations imposed upon them by the law. It is a significant fact, and one which cannot be ignored, that those who actually live amongst the mentally sick, and who are thus peculiarly cognizant of their needs, express themselves in no uncertain way as to the necessity for a policy more in harmony with the aspirations of modern medicine.

This dissatisfaction with existing conditions finds forceful expression in the presidential address delivered by Professor George M. Robertson before the Medico-Psychological Association on July 19th. As will be gathered from the report published at page 134, he began by saying: "The dominating motive which for more than a generation has directed the activities of the asylum authorities in Scotland has been the desire to make the asylum in that country an institution inspired by the same exalted principles and conducted on the same medical and nursing methods as those existing in our great general hospitals." Fortunately the aspirations thus expressed have been actually put into practice, and though Professor Robertson does not refer to his own work on behalf of the insane, the Scottish asylums owe a great deal to his courage, initiative, enthusiasm, and energy; they have been important factors in bringing the institutions to their present state of high efficiency. It is of interest in passing to note that some twenty years ago Professor Robertson expressed his ideals for the future of asylums in words almost identical with those quoted above.¹ It must be a source of much satisfaction to him to feel that his desires have been so largely realized.

In the course of his broad survey of the changes which have been introduced into the Scottish asylum system Professor Robertson observes with truth that their effect has been so great that they might be described as revolutionary were it not that the process of transformation has been so gradual. The prison features of the asylums have been largely abolished; an atmosphere has been created which is more medical, sympathetic, and human; and every effort has been made to hospitalize these institutions by the introduction of the methods employed in general hospitals for investigating, treating, and nursing disease. This record of progress is most gratifying, but there is still much to be accomplished before the treatment of mental disorder can reach that high level which psychiatrists regard as desirable. The process of hospitalization is still incomplete, and will so remain as long as the admission of patients in an early and recoverable condition continues to be obstructed by

legal technicalities. Professor Robertson spoke most emphatically. "The Scottish asylums are administered under an archaic code of laws," he said, "... and not till the cruel anachronism of those laws is removed, which after sixty-four years' service have outlived their purpose, will the asylum shed its last prison features, be cleansed of the prison taint, and be free to develop along purely medical and hospital lines." He goes on to show that there is no necessity whatever to brand a person who is sick in mind legally as a lunatic, and then commit him to detention by a magistrate as if he wore a species of criminal, before he can obtain the medical and nursing treatment his illness requires. He points out that such restrictions can be removed without evil consequences, as is demonstrated by the amazing situation that has come to pass in Scotland, where the majority of private patients paying the higher rates of board are actually being admitted to the Royal Asylums without certificates and judicial orders; and he contends, with justice, that it should be possible for the rate-aided poor to enjoy a similar privilege.

Since Professor Robertson has been intimately associated with the development of psychiatry in Scotland, it is natural that he should concern himself more particularly in his address with the asylum conditions which exist in that country. It should now be observed, however, that the aims and ideals he expresses in his presidential capacity are those which animate the Medico-Psychological Association as a whole, and the dissatisfaction he shows with the Scottish legal conditions is felt even more keenly by psychiatrists in England, where the position in respect to the lunacy law is much less favourable than it is in Scotland. The most comprehensive account of the position in England is that provided by Dr. C. Hubert Bond, the retiring President of the Medico-Psychological Association, in his Presidential address of 1921, the subject of which was "The position of psychological medicine in medical and allied services."² The possibilities of reform outlined in this address are deserving of close consideration, and may be regarded as authoritative; they carry much weight, since Dr. Bond writes not only as a psychiatrist who has taken a leading part in urging the hospitalization of English asylums, but also as a Commissioner of the Board of Control in this country. His experience enables him to appreciate the necessity for certification in certain cases, whether it be for the protection of the person and estate of the patient or for those with whom he is associated, and it also enables him to give a balanced estimate of the extent to which a relaxation of legal restrictions is possible. Dr. Bond laid emphasis on the meagre extent to which voluntary treatment for mental disorder is permitted in this country—at present, of course, only in licensed houses and registered hospitals—and strongly advocates an extension to county and borough mental hospitals of the system of voluntary admission. "The system of voluntary boarders in registered hospitals has," he said, "worked well; and, judging by the remarkable and probably exceptional circumstance that, at that moment, of the number of cases admitted into the oldest of these hospitals those received as voluntary boarders are as many as those admitted under certificates, the system finds favour. The explanation as to the difference between registered hospitals and licensed houses as respects stringency of requirements for voluntary admission is historical and accidental, and is not based on the respective merits of the two forms of institution; it would, indeed, be hard to find valid reason why the simple and formless procedure should not be available for voluntary admission to licensed houses, and equally

¹ *Journal of Mental Science*, vol. xlviii: "Hospital Ideals in the Case of

hard—except as to chargeability questions—with respect to county and borough mental hospitals to which . . . no voluntary admission is permitted. As to this denial to public mental hospitals of what would be an unquestionable boon to poorer persons who are mentally ill and desire treatment, it is useful to remember that in Scotland voluntary boarders are admissible to these institutions."

It may here be mentioned that though all psychiatrists are agreed that the treatment of the mentally deranged is handicapped by antiquated legal restrictions, there is some divergence of opinion as to the status and function of asylums in the future. On the one hand it has been suggested that an entirely new form of hospital should be created for the treatment of incipient insanity. Dr. E. Goodall has been a vigorous advocate of a scheme along these lines; he would completely divorce the new clinics which he visualizes from the existing asylums and would develop them in the closest relation with the general hospitals. He feels that this is the only way in which psychiatry can hope to gain organic union with medicine as a whole, and he regards the suggestion that early psychoses should be treated in the asylums as "one of those compromises which are so dear to the Anglo-mentality." On the other hand, a number of psychiatrists share the aim which appears to be in the mind of Professor Robertson, whose wish is to convert the existing asylums into real hospitals by taking the general hospital as its model. It is considered to be much more practicable to bring those institutions, which have been specially built and designed to meet special features in the treatment of a particular disease, up to highest medical and scientific standard than to create entirely new institutions. The respective merits of these two schemes cannot here be discussed; there would seem to be no reason why separate clinics such as Dr. Goodall describes should not develop in course of time, but as far as asylums are concerned every legal facility should be granted to enable them to develop along hospital lines in the fullest sense of the term.

Thus in regard to the immediate future we would urge the necessity for extending the privilege of voluntary admission to all mental hospitals and to all classes of the community. We may be quite sure that both the general public and the medical profession will give their full support to any legislation which has for its aim the removal of those barriers which at present obstruct the treatment of patients in the early and curable stages of mental disorder.

POST-GRADUATE EDUCATION IN LONDON.

THE reply of the Minister of Health to the deputation which had an interview with him last week as to post-graduate medical instruction in London is not, we think, to be taken as a final answer. The proposal put before him, as will be seen from the full report (published at page 130), may be summarized as a request for financial assistance in maintaining a central office in London for the organization of post-graduate medical instruction, so that the best use might be made of existing facilities, which, as we have frequently shown, are very considerable. Sir Alfred Mond's answer to the request was in fact rather ambiguous; on the one hand he made play, as was to be expected, with the need for public economy, but on the other he practically told the deputation that its proposals were too modest. The matters on which he seemed to think the deputation not bold enough in its demands were in the main two: one was that the duties intended to be assigned to the dean or principal officer were not sufficiently responsible; and the other that the proposal to make a general hospital a

part of any post-graduate medical institution in London seemed to have been dropped.

Sir George Makins, who spoke as President of the Fellowship of Medicine, had assumed as beyond argument that an adequate scheme of post-graduate education could not be financed from voluntary resources and fees alone, and the point has been so fully discussed in its bearing on higher education of every sort that he was no doubt justified in making this assumption. But Sir Alfred Mond called the principle in question when he suggested that the expense should be borne by the people who were to benefit, and asked why Americans and others who wanted information should not pay for it. It is true that he immediately qualified this by adding "in considerable proportion if not the whole." Sir Alfred Mond's second line of criticism had been answered in anticipation both by Sir George Makins and Sir Richard Luce, who spoke for the British Medical Association. The latter had pointed out that there was already a considerable demand among practitioners in this country, and that it would certainly develop further were the opportunities for obtaining such education made easier and the conditions more attractive. Sir Alfred Mond also, as has been said, called in question the view, more or less reluctantly accepted by members of the deputation, that the establishment of a central post-graduate hospital in London was not a practicable proposal. When promising the deputation to assist its propaganda in any way he could, he said that he appreciated the importance of the case laid before him, and expressed the hope that the scheme for a central hospital would not be considered as in any way dead. After this intimation the Association will probably think it desirable to go into the matter again and consider fully the arguments now advanced in favour of making a hospital an integral part of any post-graduate medical school or institution in London.

The medical profession has come to have confidence in Sir Alfred Mond's powers of getting things done when he is convinced that they ought to be done, and will not quarrel with him for proceeding with this matter at this time with caution. But caution too greatly prolonged becomes a fault; delay has already diminished some of the advantages with which London started a few years ago, and the question is not one which concerns London alone. The position in some other great teaching centres is better than in London, but in no instance has the provision for post-graduate medical instruction reached the full development which may be hoped for.

THE CONTROL OF GLYCOSURIA BY THE ISLETS OF LANGERHANS.

A NOTE on the pancreas in relation to diabetes was communicated to the meeting of the American Physiological Society at the end of last year and a brief report was printed in the *Proceedings*.¹ It described certain work done in the Physiological Department of the University of Toronto by Professor J. J. R. Macleod and Dr. F. G. Banting and Mr. C. H. Best. They started from the hypothesis that the reason why the usual extracts of pancreas do not satisfactorily demonstrate the presence of an internal secretion acting on carbohydrate metabolism was because the internal secretion was destroyed by the digestive enzymes also present in such extracts. That the islets might be the organ of pancreatic internal secretion was first suggested by Laguesse, a French anatomist. In 1912 Kirkbridge found that healthy islets were present in the atrophic tissue of the gland after ligation of the ducts, and in 1917 Kamimura confirmed the fact that the islets remained normal, and stated that the animal did not develop glycosuria as long as the islets were left intact.

¹ *American Journal of Physiology*, lix, p. 479. A full preliminary paper by Banting and Best is published in the February issue of the *Journal of Laboratory and Clinical Medicine*.

It is well known that excision of the pancreas produces in dogs severe and fatal diabetes. The conclusions to be drawn from previous work were considered to be that the secretion produced by the acinous cells of the pancreas is in no way connected with carbohydrate utilization, that all injections of whole-gland extract have been futile as a therapeutic measure in defects of carbohydrate utilization, and that the islands of Langerhans are essential in the control of carbohydrate metabolism. In order to test the hypothesis, they had evolved the Toronto workers took advantage of the fact that acinous cells degenerate in seven to ten weeks after ligation of the ducts, whereas the insular cells were at that stage at least unaffected. Ten weeks after ligation of the pancreatic ducts the degenerated gland was removed and extracted with ice-cold Ringer's solution. This extract when injected intravenously or subcutaneously invariably caused marked reduction of the percentage of sugar in the blood and the amount of sugar excreted in the urine of diabetic animals. Extracts of liver, spleen, or boiled extract of the degenerated pancreas were found to have no effect. They found also that glucose given intravenously or by the mouth is retained by diabetic animals if adequate doses of the degenerated pancreas are also administered, and that the clinical condition of the animal is improved; the estimation of the amount of haemoglobin gave the same result before and after the experiment. Rectal injections were not effective. The neutral extract kept in cold storage retained its potency for at least seven days. Subcutaneous injections were found to have a less rapid but more prolonged effect. If these experimental observations prove clinically applicable to man, clearly a magnificent contribution to the treatment of diabetes will have been made. Ever since it was first shown that diabetes commonly depended on a pancreatic lesion some such remedy as that now described has been hoped for and sought after. We trust that before long sufficient clinical results will be forthcoming to show whether the sanguine expectations the Toronto observations will raise are well founded.

THE NATURAL HISTORY OF THE MOUNT EVEREST REGION.

News reached London on Saturday last that the third and final attempt to scale the summit of Mount Everest had been given up. The leader, General Bruce, reported a disastrous avalanche which killed seven porters and nearly caused the death of Mr. Mallory, Dr. Somervell, and Mr. Crawford. The expedition has in consequence been abandoned; but Mr. Finch and Captain Bruce's achievement of reaching an altitude of 27,200 feet is some compensation for the failure to conquer the greatest mountain in the world. These recent events give special interest to the July issue of the *Geographical Journal*, which contains Sir Francis Younghusband's presidential address at the anniversary meeting of the Royal Geographical Society, an editorial general note on the Mount Everest Expedition, 1922, and a paper on the natural history of South-Western Tibet by Dr. A. F. R. Wollaston, the medical officer and naturalist of last year's reconnaissance expedition under Colonel Howard-Bury. As Sir Francis Younghusband remarks, the 1921 expedition thoroughly reconnoitred the approaches to Everest and settled beyond dispute the easiest line of assault on the summit; but besides having achieved its main object it accomplished much other work of value. A general survey of the whole unmapped region, a detailed survey of the immediate environs of Mount Everest, and a geological reconnaissance of the area were made. Dr. Wollaston formed a valuable collection of the mammals, birds, and plants, and together with other members of the party brought back beautiful and interesting photographs. His paper on the natural history of the region, read before the Society in February, is now published in full with pictures. A remarkable feature of Tibet is the tameness of the wild animals, and out of respect for the Buddhist religion the party had to refrain from shooting in the neighbourhood of monasteries and villages where birds mostly congregate; nevertheless, he made a considerable collection of mammals

and birds. A large number of dried plants and seeds also were brought back, and many of the seeds have been sown in English soil. Naturalists will enjoy Dr. Wollaston's charming account of these mountainous regions. Above 14,000 feet the vegetation is stunted: "This is Tibet proper, and henceforward you may travel for many hundreds of miles and hardly see any plant more than a few inches high. . . . Animals are few and far between." The only mammals commonly seen are the small mouse-hares, or pikas, sometimes called whistling hares, though they are not hares and do not whistle. During an excursion to one of the principal passes leading from Tibet to Nepal the party was astonished to find at 12,000 feet an abundance of very active leeches. An interesting plant found between 17,000 and 18,000 feet is a dwarf blue hairy delphinium. The Tibetans dry the flowers of this plant and use them as a preventive against lice, but without much success. "When a Tibetan dies his body is undertaken by the professional butcher, who cuts it up and exposes it on the hills to be disposed of by the vultures and wolves. A body tainted with the delphinium flowers is unpalatable to the scavenger, and it is well known that a man must have been wicked in life whose body is rejected by the vultures and wolves." Animal life above 17,000 feet is scanty. Birds of a few species visited the camps, and mice of some kind came into the tents at 20,000 feet and ate the food, but escaped without being seen. The tracks of fox and hare were seen still higher, and at about 21,500 feet the explorers came across the tracks of the legendary "snow men" which afforded such fun to so many people. There can be no doubt, Dr. Wollaston thinks, that these tracks were made by a wolf loping along at a good gait; the snow was soft, and the tracks had got partially merged together. The paper ends with a note about the smells of Tibet—some vile and others delightful. It was discussed from various points of view by Sir David Prain, then Director of the Royal Botanic Gardens, Kew; Sir Sidney Harmer, Director of the Natural History Museum; Mr. W. R. Dykes, Secretary of the Royal Horticultural Society; Mr. N. B. Kinnear; and Mr. Freshfield. The President closed the proceedings by thanking Dr. Wollaston for his most interesting address, and congratulating him upon the general good health of the party under his charge.

THE FOUNDER OF THE NEWCASTLE MEDICAL INSTITUTE.

LAST year, during the annual meeting at Newcastle-on-Tyne, Sir Clifford Allbutt opened the Medical Institute given to the profession in the district by Dr. J. W. Smith, of Ryton-on-Tyne, a former President of the North of England Branch of the British Medical Association, as a memorial to his son, Dr. J. Wilkie Smith, a young man of great promise who died some seven years ago. In the course of his remarks on this occasion Sir Clifford Allbutt said that he had felt all his life, especially in younger days, the isolation of medical men, particularly in country districts. Town men also were busy, their hours uncertain, and they too got isolated, with the consequence that misunderstandings arose which could be cleared away if they met each other socially in an institute such as that established by Dr. J. W. Smith. The founder hoped that in addition to the social side the institute would foster scientific interests also, and Sir Clifford Allbutt concluded by observing that it was a great pity that a good deal of knowledge possessed only by general practitioners never got into any books, simply because authors were ignorant of it. Professor David Drummond, who presided at the ceremony, spoke of the great value of such an institute to members of the profession in and about Newcastle. Its advantages have been widely appreciated, and many medical and social meetings have been held there. To mark their gratitude for so generous a gift the members have cordially accepted the suggestion of the committee of the institute that a portrait of Dr. J. W. Smith should be painted and hung within the building. The work has been undertaken by

Mr. Hodgson Campbell of Newcastle. A small fund has been opened, to which members of the institute have subscribed, but the committee think that there are other medical men and women who may wish to express their appreciation of Dr. Smith's effort to further the interests of the profession and promote that state of harmony and goodwill which is so desirable and essential. Donations, from 10s. 6d. to 2 guineas, will be gratefully acknowledged by the honorary secretary, Dr. Stanley Robson, the Medical Institute, 7, Windsor Terrace, Newcastle-on-Tyne.

EXPENDITURE ON ALCOHOL IN HOSPITALS.

A PAINSTAKING analysis of the expenditure on alcohol at two large voluntary hospitals over a period of more than a century was given by Mr. C. J. Bond in his presidential address to the Society for the Study of Inebriety on July 11th. The hospitals in question were the Leicester and Derby Royal Infirmaries, and the period was from 1810 to 1920. In both the histories there were certain more or less coincident periods in which the average yearly expenditure on alcohol for each patient admitted rose to a comparatively high figure or fell to a comparatively low one. In 1810 at Leicester the amount spent on alcohol was £530 for 700 patients and staff, or about 15s. per head. A relatively high expenditure on alcohol continued until 1825 at Derby and 1835 at Leicester; this was the lean and troubled period after the Napoleonic wars. The consumption of alcohol fell between 1830 and 1860, and rose again between 1850 and 1880, and in these twenty years the high-water mark of alcohol consumption, both institutional and national, was reached; the period corresponded to great industrial activity and prosperity. From 1880 to 1900 there was a low consumption of alcohol, due, Mr. Bond believed, to the fact that the years of temperance propaganda were at last bearing fruit. A further sharp decline took place from 1900 down to the time of the war. During the first part of the war, and in the case of Leicester down to the spring of 1918, the consumption of alcohol in the institutions was almost negligible, but both institutions showed a marked post-war reaction, which continued until the trade depression of 1921. This reactionary rise after the war years was almost entirely due to the increased consumption of wines and spirits. It had been argued that the rise could be accounted for by the admission and treatment of a considerable number of soldiers, many of them with severe wounds, but the continuation of the increase at Leicester after the period when soldiers were no longer admitted was not in harmony with this suggestion. Altogether there was a concurrence between institutional and national expenditure on alcohol, making it evident that hospital practice was not yet founded on scientific knowledge as to the action of alcohol on the human organism. It could not be claimed that the hospitals had acted as pioneers in moulding public opinion or influencing national conduct with regard to the use of alcohol, although they did seem to have discountenanced it as a beverage, especially in later years. But the use of alcohol in the treatment of disease by medical officers in hospitals had largely followed national habit and custom. Periods of high national consumption of alcohol coincided generally with periods of high institutional expenditure on alcohol. It must be said, however, that if the voluntary hospitals had not acted as pioneers in temperance reform, they had done salvage work in rescuing the victims of alcoholic excess. He had been at some pains to ascertain the magnitude of the call made on the accommodation and the medical and nursing services at Leicester Royal Infirmary from November, 1910, to April, 1913, by persons who were treated as patients there while under the influence of drink. During this period 243 drunken patients were treated, or an average of about 100 a year, and if this held good for the whole country—and Leicester was a soberer town than most—it meant that 10,000 people were admitted to the hospitals every year as a direct result of intoxication. This, of course, was only part of the levy which the drinking habits of the people exacted

from the hospital services. Hospital wards and out-patient departments were largely used by those whose diseases and disabilities were the result of alcoholic indulgence. In conclusion, Mr. Bond expressed the opinion that the time had come for hospital authorities and administrators to speak out plainly on this matter. The public should know the magnitude of the financial burden and the great loss of institutional time, money, and service which occurred in remedying the injury done by ignorant, selfish, and anti-social conduct. It was also necessary that hospitals up and down the country should cease to be swayed by fashion and tradition in the matter of the use of alcohol in the treatment of disease.

THE FOULERTON PROFESSORSHIP AND STUDENTSHIPS.

THE Council of the Royal Society gives notice that it has created the Foulerton Research Professorship, and that the appointment of a professor will be made on the advice of a committee of Fellows called "The Foulerton Research Fund Managing Committee." The stipend will be £1,400 a year, and the duty of the holder of the professorship will be to conduct, in a place approved by the committee, such original researches in medicine or the contributory sciences, on lines approved by the committee, as shall be calculated to promote the discovery of the causes of disease and the relief of human suffering. The appointment will be in the first place for five years, but may be renewed for further periods of not more than five years at a time. The normal retiring age will be 60, but a professor may be continued in exceptional cases for a further specified period. Arrangements are being made for superannuation under the Federated Superannuation System for Universities, and the professor will be required to devote the whole of his time to research. The holder of a paid academic or other scientific appointment may, however, be nominated, provided the committee is satisfied that the duties of such other appointment occupy only a subsidiary portion of the applicant's time and that its retention would not interfere with the discharge of the duties of the professorship as essentially a whole-time research appointment. In such case the committee would recommend a reduction of the stipend, of such amount, however, as shall not reduce the total annual income of the professor from his paid appointment and from the fund below £1,400. The appointment will only be made if candidates of sufficient distinction present themselves. The Royal Society also gives notice that it is prepared to appoint one or more Foulerton research students, the stipend being £700 a year. The duties of a Foulerton research student will be to conduct researches in medicine or the contributory sciences under the supervision and control of the committee, to whom the student will be required to report from time to time on the progress of his work. The studentship will be for three years, but may be renewed from year to year until it has been held for a maximum period of six years from the first award. In recommending a person for appointment as student, the committee will have in view the expressed wish of the donor that awards should be made especially to young workers. The stipend is £700 a year, and a studentship will normally be regarded as a whole-time appointment, but in exceptional cases the holder may be allowed to retain a paid teaching post; in that case the committee may recommend the payment of such stipend as it may think fit. A candidate may be called upon to show that he or she is and that his or her father and paternal grandfather are, or were at the date of their respective deaths, of British nationality. Unless the Council directs to the contrary, arrangements will be made for the superannuation of a Foulerton studentship under the Federated Superannuation System for Universities. Applications for the Professorship or Studentship, for both of which members of either sex will be eligible, must reach the Royal Society not later than October 31st next. Further particulars will be found in our advertising columns, and full particulars can be had on application to the Assistant Secretary of the Royal Society, Burlington House, W.1.

THE ROCKEFELLER FOUNDATION IN 1921:

IN his review of the Rockefeller Foundation's work for 1921 Mr. George E. Vincent,¹ the President, sums up its various activities under twenty-one heads, of which the following may be quoted: The formal opening of a complete modern medical school and hospital in Peking, and assistance to twenty-five other medical centres in China; the provision of 157 fellowships in hygiene, medicine, physics, and chemistry to representatives of eighteen countries; campaigns against malaria, hookworm disease, and yellow fever; the appropriation of 3½ million dollars to rebuild and reorganize the medical school and hospital of the Free University of Brussels; and the supply of experts in medical education and public health for counsel and surveys in many parts of the world. These services were carried out partly by the Foundation directly, but chiefly through its departmental agencies—the China Medical Board, the International Health Board, and the Division of Medical Education. He quotes the aphorism of a successful American health officer, "Cure looks through the microscope, prevention through the telescope"; he anticipates the time when a case of illness will be regarded as a reflection upon the doctor's vigilance, and refers to the four stages in the progress of preventive medicine: first, the control of the physical environment through pure water, milk, and food supplies, and adequate sewage and refuse disposal; then control of diseases due to other factors, such as those of industrial origin; thirdly, personal hygiene; and lastly the dawning phase of economic, social, and mental influences. Mental hygiene is a part of public health, and the National Committee for Mental Hygiene has been liberally financed by the Rockefeller Foundation. An account is given of the School of Hygiene and Public Health at the Johns Hopkins University, which is supported by the Rockefeller Foundation, and supplements the activities of the Harvard school, where such pioneer work in industrial medicine has been carried out. With the support of the Rockefeller Foundation a "pay" clinic at moderate cost was opened by the Cornell University Medical School in New York in November, 1921, a complete diagnostic examination being provided for 10 dollars on cases sent there by medical men. On the day that the clinic opened there were 700 patients, and since then the number has steadily increased. The results in the prevention of yellow fever in South America are most encouraging, but one of the Rockefeller Institute workers, Dr. Howard B. Cross, died of the disease on December 26th, 1921, at Vera Cruz, where the Public Health Laboratory has now been named the Howard B. Cross Laboratory. The full report of the Rockefeller Foundation, including detailed reports of the International Health Board and the China Medical Board, for 1921 will when published later be sent to libraries, and may be obtained on application by other institutions or individuals.

WHITE-LEAD POISONING.

AMONG industrial diseases lead poisoning is perhaps that to which most persistent attention has been paid not only in recent times but in past ages. Until the end of the last century more attention was paid to the treatment of those affected than to the prevention of the ailment, but after the appointment of medical inspectors on the staff of the Factory Department of the English Home Office investigations were made with a view to the adoption of preventive measures. In 1908 Mr. Herbert (now Lord) Gladstone, who was Home Secretary at the time, appointed a departmental committee to consider the dangers attendant on the use of lead in the manufacture of china and earthenware and to report how far these could be obviated or lessened. A large number of potteries were visited by the committee, who were assisted in their inquiry by the evidence among others of representatives of the manufacturers and of the workpeople.

After two years' painstaking investigation a most valuable report was issued, containing recommendations many of which have been adopted, with the best results. At later dates departmental committees have investigated and reported on the danger attendant on the use of paints, lead compounds, etc., and a more recent inquiry into the same question has been held by the New South Wales Board of Trade at the instigation of the Minister for Labour and Industry of that colony, which asked for a report as to whether white lead as used in the painting industry is so injurious to painters and other workmen engaged in the industry as to make it expedient or necessary to regulate, restrict, or prohibit its use in paints or pigments. The report of the Board, which has recently been issued, is an elaborate document of nearly 800 pages; much of this space is given to recording the 10,000 questions addressed to the fifty-two witnesses called before the Board and their replies thereto. Among the witnesses were seven medical practitioners; several Government officials, mining engineers, master painters, and operatives. The conclusion the Board came to was that lead as used in the painting industry—that is, lead principally in the form of a basic carbonate, or white lead—is a substantial cause of injury and death to painters and other workmen engaged in the painting industry, but that immediate prohibition or restriction of the use of white lead is not the appropriate remedy for these evils. There would, in the opinion of the Board, be no more reason for the prohibition of the use of white lead in paints than there would be for the prohibition of lead mining or indirectly for the prohibition of the mining of precious metals that are to be found in geological association with lead bodies. "Lead poisoning being a preventable disease, it would indeed be a desperate situation if the only means of prevention were the abolition of the use of lead." The report refers at some length to the regulations of the Home Office in force in this country, and recommends the adoption of somewhat similar regulations in New South Wales. Special stress is laid on the importance of attention to personal hygiene, of a properly arranged dietary, and the avoidance of intemperance. The part to be played by employers in reducing dust risks and providing efficient ventilation of factories, and installing suitable washing appliances and meal rooms, is emphasized, and proper medical supervision is recommended.

THE R.A.M.C. MEMORIAL.

THE ceremony at the unveiling at Westminster Abbey of the memorial tablet to the officers and men of the Royal Army Medical Corps, which included, of course, a large number who were serving with temporary commissions or for the period of the war, was singularly simple, beautiful, and impressive, and few who were present can have been unmoved. The words spoken by the Duke of Connaught, Colonel-in-Chief of the Corps (as reported elsewhere in this issue), in making the gift of money to the Abbey and unveiling the tablet, and of the Dean in acceptance, were few, simple, and well chosen. The service consisted of a few prayers, two well-known hymns, and the singing of the cantation of the faithful departed. The music was exquisitely rendered by the Abbey choir, reinforced by the band of the Welsh Guards. As the term "cantation" is not well known in this country, we may explain that in the sense in which it is here used it is defined in the *New English Dictionary* as a short ode or hymn in praise of a saint which occurs in the offices of the Eastern Church. The invention of the cantation form is traditionally ascribed to St. Romanus, who lived about A.D. 500. The primary meaning of the word appears to be a roll or scroll, and the legend is that the saint was inspired to compose these hymns by the eating of a roll or scroll. But this is merely popular etymology, and it has been suggested that the word is, in fact, a corruption of the Latin *canticum*, a song. The words of the cantation sung on July 13th were as follows: "Give rest, O Christ, to Thy servant with Thy saints, where sorrow and pain are no more, neither sighing, but life everlasting. Thou only art immortal, the Creator and Maker

¹ The Rockefeller Foundation: A Review for 1921. By George E. Vincent, President of the Foundation. New York, 1922. (Pamphlet, pp. 59. No price.)

of man: and we are mortal, formed of the earth, and unto earth shall we return: for so Thou didst ordain, when Thou createdst me, saying, Dust thou art, and unto dust shalt thou return. All we go down to the dust; and, weeping o'er the grave, we make our song, Alleluia!"

SPECIAL NUMBER OF THE "GLASGOW MEDICAL JOURNAL."

THE July number of the *Glasgow Medical Journal* contains a number of articles bearing more or less directly on the Annual Meeting of the British Medical Association in that city next week. Of two articles, that by Mr. Mungo Ferguson, on some medical manuscripts and books in the Hunterian Library of the University, and by Mr. Walter Hurst, on some possessions of the Royal Faculty of Physicians and Surgeons, we published a preliminary note last week. The number also contains a paper by Mr. C. R. Gibson, F.R.S.E., on Dr. Charles Morrison of Greenock, who in 1753 published an article entitled "An expeditious method of conveying intelligence." It was, in fact, a method of electric telegraphy devised fifty years before the discovery of the electric current. Morrison's apparatus consisted of twenty-six metal wires, erected between two cottages and insulated from one another by fixing them in blocks of glass at short intervals along the route. At each station the ends of the twenty-six wires were fixed in a piece of solid glass, each wire projecting through the glass to a distance of about six inches; on the end of each was suspended a short vertical wire with a small metal ball at its extremity. Beneath each ball at a distance of about one-eighth of an inch was a letter of the alphabet. With this apparatus Morrison succeeded in spelling out words, and he even went so far as to suggest that the reading might be made by sound if the balls were replaced by bells. Mr. Gibson's account of the early history of electricity is extremely interesting, and he recalls the fact that it was to another doctor—Dr. William Gilbert of Colchester—that the earliest inquiries were due. The number also contains a paper by Dr. G. H. Edington on the "Discoveries" of Maister Peter Lowe, who, as has been mentioned in previous notes in our pages, was the founder in 1599 of the Faculty of Physicians and Surgeons. Dr. Edington gives extracts from Lowe's volume published in 1612 and accompanies them with a number of interesting comments. There are also two reminiscent articles, the one by Dr. Freeland Fergus of Glasgow, who has a good deal to say about "old G.," Professor (afterwards Sir) William Gairdner, President of the Association when it met in Glasgow in 1888; of Sir George Macleod, who on that occasion delivered the Address in Surgery; of Dr. George Buchanau, who was President of the Section of Surgery; of Dr. McKendrick, Professor of Physiology; of Dr. Joseph Coats, Professor of Pathology; of Lord Lister; and of Dr. Finlayson, about whom one uncanny story is told. He would make an unwary student write a prescription and when Finlayson foresaw that the result would be more than ordinarily awful he would have it made up and compel the prescriber to take a dose of his nauseating compilation. The other reminiscent article is by Sir Dawson Williams, Editor of this JOURNAL, who in response to a request to write an article on the "old lions" of the British Medical Association has written some notes on the men who were most active in its counsels during the ten years before and the ten years after its Annual Meeting in Glasgow in 1888.

A very attractive *Book of Glasgow*—the work of many hands—has been prepared under the direction of the Printing and Publishing Committee for the benefit of members of the British Medical Association visiting Glasgow during the Annual Meeting. It is a handsome book of more than 250 pages, with many illustrative plates, including as frontispiece a portrait of the President, Sir William Macewen. As the Chairman of the Committee, Dr. William Snodgrass, says in his preface, this is not intended to be in any sense a guide-

book to the city and its institutions. The object has been to present a series of impressions of the second city of the Empire, though the university and medical institutions are treated with greater fullness than the word "impressions" might suggest. Next week we hope to discuss in more detail this interesting volume.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Mental Institutions.—Mr. R. Richardson asked, on July 12th, whether the Minister of Health proposed in his new Mental Bill to introduce into England the section of the Scottish Lunacy Act which authorized without certification the compulsory detention of an individual for six months in a mental institution on the word of one doctor without any provision for inquiry or appeal. Sir Alfred Mond said that no such provision was contemplated, nor must he be taken as accepting Mr. Richardson's interpretation of the Scottish Act, the proper construction of which was, he understood, a matter of considerable doubt. In reply to a further question by Mr. Richardson, Sir A. Mond said that on January 1st, the latest date for which figures were available, there were 127 voluntary boarders in licensed houses and 165 in registered hospitals in England and Wales. One hundred and sixty-nine voluntary boarders were certified during 1921, and 421 left of their own accord. The period of residence varied from a few days to several years, and the average was probably under six months. He had not the Scottish figures.

Health and Unemployment Insurance.—In answer to Mr. T. Thomson, on July 12th, Sir John Baird stated that out of every 20s. of the total amount received from all sources into the National Health Insurance Fund it was estimated that 12s. 2½d. went in benefit, 5s. 1½d. to reserve, and 2s. 8d. on administration. The corresponding figures for the unemployment fund were 17s. 10d. in benefit and 2s. 2d. in administration, including the cost of dealing with insured workpeople at unemployment exchanges. The amount estimated to be paid out in unemployment benefit during the current financial year was substantially greater than the total contribution, the balance being met by borrowing.

Finance Bill Amendments.—The Chancellor of the Exchequer, on July 12th, secured the addition of several new clauses to the Finance Bill on the report stage. One of these referred to the entertainments duty. Down to the present the amount of allowance conceded for expenses under the entertainments duty in respect of an exhibition for charity purposes has been 20 per cent. The Chancellor agreed to increase the limit from 20 to 30 per cent. of the receipts, as the smaller figure was not sufficient to encourage such exhibitions being given. Mr. Myers urged that where it could be established that all the net proceeds would go to a charitable object the Chancellor of the Exchequer should keep his hands off the entertainment receipts; to ensure the success of these events artists ought to be engaged. Sir Robert Horne replied that such a concession would leave a large loophole for abuse. People would be willing to give entertainments ostensibly for a charitable object, but from which in the end nothing appreciable would go to charity because everything was taken up by expenses. Another new clause was to the effect that allowances granted by the Minister of Pensions under a Royal Warrant order or order administered by him to widows of members of the naval, military, or air forces of the Crown in respect of their children should not be reckoned in computed income of such widows for income tax. On Clause 35, on July 13th, Sir Robert Horne moved an addition to exempt from Corporation Profits Tax "the profits of a company which is established solely for the advancement of religion or education, and which, under its memorandum or articles of association, is prohibited from distributing any part of its profits to its members." He said that the question had been raised by Mr. Rawlinson, member for Cambridge University, who had presented very cogent reasons. An instance had been given in which an educational organization had borrowed money and set up an institution, and was then compelled to borrow to pay the Corporation Profits Tax, although the institution was being run at a loss. The addition was agreed to. Sir Robert Horne promised to consider, before next Budget, the position of associations incorporated by Royal Charter.

Brief Notes.

Sir Alfred Mond, in reply to Mr. Betterton on July 18th, said he hoped to introduce the Smoke Abatement Bill at an early date. Sir Alfred Mond has stated that the Ministry of Health is about to issue a memorandum on the Schick method of prophylaxis of diphtheria, containing information as to the proper use of the test. A description of this method, founded on a report made to the Ministry by Dr. S. Monckton Copeman, F.R.S., and Sir G. S. Buchanan, C.B., was published in our columns of December 10th, 1921 (p. 994).

THE Congress of French Alienists and Neurologists will be held at Quimper in the first week of August, when the following subjects will be discussed: (1) Mental disturbances in epidemic encephalitis, introduced by Truelle and Petit; (2) lesions of the central nervous system in motor agitation and in rigidity, introduced by Anglade; (3) welfare of the insane, introduced by Courbon.

THIRD INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE.

This Congress was opened at the Royal Society of Medicine on Monday morning, July 17th, by the Earl of Onslow, Parliamentary Secretary of the Ministry of Health. He was supported on the platform by Sir Humphry Rolleston, P.R.C.P., Sir Anthony Bowly, P.R.C.S., the Master of the Society of Apothecaries, Major-General Sir F. Smith, Dr. Triet-Royer (President of the International Society of the History of Medicine), Sir D'Arcy Power (Vice-President of Honour of the Congress), Dr. Charles Singer (President), Sir Arthur Keith, Dr. J. D. Rolleston (General Secretary), Mr. W. G. Spencer, F.R.C.S. (Treasurer), and others. There was an excellent attendance of members and friends.

Lord Onslow's Address.

Lord Onslow, after declaring the Congress open, gave an interesting address, the first part of which he delivered in French. He first apologized on behalf of the Minister of Health for his absence that morning. It was a great disappointment to Sir Alfred Maud that urgent public duties prevented him from being able to welcome the members in person. On the part of the Government, of the Minister of Health, and his colleagues at the Ministry he offered a most cordial welcome to the visitors from abroad and wished the greatest success for the Congress. That this was the third meeting of the kind which had been held was in itself a proof that the subject of the history of medicine was becoming more highly appreciated and understood. Previous meetings had been held in Paris and in Antwerp, and he hoped this subject of the history of medicine was being more highly appreciated—and this was of the greatest importance, for in all branches of human knowledge and experience, in politics and administration, no less than in science, the future could not be guided without both the knowledge and understanding of the past.

Lord Onslow then briefly reviewed the stages in the history of medicine from the time of Hippocrates and of Greek medicine in Rome, through the Middle Ages, when medicine was mainly the province of Orientalists, up to the revival of learning in Western Europe after the fall of Constantinople. Here in England, he said, Thomas Linnere might perhaps be counted as the earliest of our great physicians and the founder of modern medicine in this country. Less than a century after his death came the discovery of the circulation of the blood by William Harvey, who laid the foundation of all modern physiology. Thirty years later Thomas Sydenham set out the great principles of observation of disease. In the eighteenth century John Hunter did for pathology what William Harvey had done for physiology; and in the nineteenth century three great steps in medicine were taken by men whose names were household words—Edward Jenner, James Young, and Joseph Lister. There were no greater events in the history of medicine since the age of antiquity than these three discoveries—vaccination, chloroform anaesthesia, and the antiseptic system.

Lord Onslow said in conclusion:

"This interpretation of the history of medicine, which gives a knowledge of its progress in the application of the laws of nature to the treatment of disease, is one of the most fruitful aspects that can be borne in mind. There is one other brilliant chapter of English medicine to which I may briefly refer, and that is the knowledge and application of the principles of preventive medicine. We have now had nearly a century of experience of the application of preventive medicine to the health of communities in this country. We have still much progress to make, but, speaking generally, the science of public health is as advanced in England as in any other country of the world, and future centuries will look back upon this time as a time of progress, when the history of medicine was widened to comprehend the large and urgent questions of sanitation, of the control of the food and water supply, the stamping out of epidemics, of the protection of maternity, of infant and child welfare, and of the establishment of a sanitary cordon and of international co-operation in questions of health. It is an honour as well as a pleasure to open this Congress and to wish for it the greatest possible success. It is hoped that it will stimulate the study of this question, that it will inspire research and investigation, and that it will add to the general culture and learning of the profession of

medicine. There is another aspect or interpretation to the history of medicine—namely, the history of our knowledge of particular diseases and pestilences, a subject which has been worked at in this country in modern times by Dr. Charles Creighton, whose famous book on the *History of Epidemics in Britain* has for many years been a classic. We might well study the history of leprosy, of plague, of sweating sickness, of small-pox, and even of influenza, and from such a study we derive a knowledge of how these diseases have been dealt with in the past, which is full of interest and importance in regard to their control in the present. Much has been done in this regard, and we now know a good deal about the prevalence of leprosy and plague in past centuries. The foundations of old leprosy houses and plague hospitals and plague pits are still to be found in all parts of these islands, and the records made by past observers of these scourges bring valuable information to the hands of the administrator. We recognize most gladly the splendid work which has been done abroad in this direction, but we are justly proud of our own history. For we have had in England not only famous historians of medicine such as Dr. Freind, Adams, but we have to-day happily still with us Sir Clifford Allbutt, the venerable Professor of Physic at Cambridge, and Sir Norman Moore, the historian of St. Bartholomew's Hospital, the President of Honour of our Congress. It is but yesterday that we had in our midst Sir William Osler, the brilliant Professor of Medicine at Oxford, whose work as a historian of medicine and as the inspirer of the study of the history of medicine stands in the very front rank. With the medical profession in all countries we mourn the loss we have sustained in his death."

Lord Onslow then received and shook hands with each of the official delegates, who were present from the following countries: Belgium, Denmark, Egypt, France, Greece, Italy, the Netherlands, Portugal, Rumania, Spain, Switzerland, and the United States.

Presidential Address.

Dr. SINGER, President of the Congress, then took the chair, and welcomed the members to what he believed to be the first attempt at an international reunion of doctors in England since the great war. It was in the fitness of things that history should be the first branch of the science to bring men together again, and that Belgium, being on the borders of so many different linguistic regions, should be the first place of reunion. Those who assisted at such a Congress believed that the history of medicine was not only a subject worthy to distract them and amuse them, but a discipline full of humanity and philosophy, covering more than half of the field of studies known under the name of history of science. We were supposed to belong to the era of evolution, and science, amongst all the subjects which man interested himself in, was changing most rapidly. The thoughts of our century were separated from those of the past by the fertilizing doctrine of evolution. This doctrine was one way of presenting the truth, and at least it had contributed to stimulate the historian's studies in biologicistic research. The history of medicine gave to the medical man in practising his profession or in carrying out his scientific researches the only footing to withstand the cynicism of this period of his life, when the ardour of youth had disappeared without being replaced by the mellowness of age. With this support the doctor could find joy in his work and pride in his profession. In England the foremost writers of the history of medicine had been men who gave the time they could spare from the exercise of their profession. The President of Honour, Sir Norman Moore, and Sir Clifford Allbutt were the two pioneers and veterans in England of the history of medicine. The Vice-President of Honour, Sir D'Arcy Power, and the Treasurer, Mr. Walter Spencer, by their skill, their knowledge, and their kindness had acquired the affection and respect of all doctors whose mother tongue was English; and with them he would associate the name of Dr. Raymond Crawford. In conclusion, Dr. Singer expressed gratitude to his indefatigable colleagues, Dr. J. D. Rolleston and Mr. C. J. S. Thompson.

National Delegates' Reply.

Dr. LAIGNE-LAVASTINE, delegate from France, on behalf of the other national delegates, said, in reply: "To greet the British Government and doctors is for me an honour and pleasure; it is an honour to represent before one of the most powerful social organizations in the history of the world our society, born but yesterday, and the joy of saying aloud all the good things I think of my colleagues to myself. In the

namo of all the delegates, present and absent, I address our heartfelt thanks to our present hosts, and express to them our pleasure in being here."

Sir D'Arcy Power, in the name of the British section of the Society of the History of Medicine, offered a cordial welcome to all the members. England considered it a great honour that she should have been chosen for the third meeting, and he felt sure that this was a sign of the increasing interest in the history of medicine in this country. He hoped all the members would carry away with them recollections of a very pleasant meeting.

Dr. Tricor-Royer responded, saying he felt assured that the present Congress would be crowned with success. The increasing interest in the subject was noticeable in both the Antwerp and Paris meetings, but here there was the perfect discipline and organization to bring it to perfection. The next meeting of the society should be held at Brussels next year, when His Majesty the King of the Belgians would be pleased to take it under his patronage. Amongst the subjects for discussion would be Oriental, Greco-Roman, Byzantine, and Middle Age healing arts, and medical science during the war.

Reception at the College of Physicians.

In the afternoon a reception was held at the Royal College of Physicians of London. The President, Sir HUMPHRY ROLLSTON, in cordially welcoming the members of the Congress, conveyed to them the gracious message from Sir Norman Moore, "an entire lover of the College," whose great work in promoting the study of medical history in this country had been appropriately recognized in his position as President of Honour of the Congress. In 1518, when Thomas Linacre, perhaps the most learned man of his time, obtained a Royal Charter from Henry VIII, medicine was scarcely better than a mechanical art, and there was no society in this country, save the religious foundations and universities, solely devoted to the pursuit of knowledge. Anxious to raise the standard of the medical profession, Linacre founded the College on the lines of the Italian universities of Bologna and Padua, and the early Fellows of the College were first learned men and then physicians. From 1518 to 1614 the College occupied Linacre's house in Knight Rider Street, and John Caius, the founder of the science of anatomy in England, did much for the organization of the College. The next period (1614-66) at Amen Corner was noticeable for Harvey's Lumleian lectures, in which his discovery of the circulation was made public, and for the issue of the first pharmacopoeia of London in 1617. Sydenham and Thomas Browne were connected with the College; their fame reflected credit thereon. The fire of London destroyed the College, Harvey's museum, and most of the library in 1666, and for the next 150 years the College was lodged in Warwick Lane, in a building designed by Sir Christopher Wren, the dome of which was described by Garth as:

"A golden globe placed high with awful skill,
Seems to the distant sight a gilded pill."

Among the famous Fellows during this period were Sir Hans Sloane, President of the Royal Society, whose collections formed the nucleus of the British Museum; Richard Mead, the patron of arts and literature; Arbuthnot, who invented the character of John Bull; Garth, the author of *The Dispensary*; Matthew Baillie, who wrote the first book wholly devoted to morbid anatomy; Freind, the historian; Heberden, of the *Commentaries*; and Thomas Young, of the undulatory theory of light. In 1825 the College moved under the auspices of Sir Henry Hallford to its present site, and since then the great names connected with the College included those of Bright, Addison, Thomas Watson, and William Jenner. The President then called on Dr. Chaplin to describe the library.

An interesting display of rare books, silver, plate, prints, and other objects was set out in the Library and Censors' Room, and the Harveian Librarian, Dr. ARNOLD CHAPLIN, in his brief but most interesting survey of the history of the Library, indicated some of its treasures. The members of the Congress were afterwards entertained to tea by Sir D'Arcy and Lady Power at their house in Chandos Street, Cavendish Square.

Prehistoric Human Skulls and the Evolution of Man.

At the largely attended conversation given by the President and Mrs. Stager to the members of the Congress

on the evening of July 17th, Professor G. Elliot Smith, F.R.S., gave an address on recent discoveries of fossil human remains and their significance in the evolution of man.

Professor ELLIOT SMITH said that the knowledge of extinct species of the human family was comparatively recent. Until 1848 no remains of any human being who did not belong to *Homo sapiens* had been discovered. In that year, while some work was proceeding on the defences of Gibraltar, an officer of the Royal Engineers unearthed the first human skull which did not belong to that order. The enormous importance of the discovery was not at first realized, and in the meantime, in the Neanderthal valley in Germany, another skull was found of similar characteristics, so that the name *Homo neanderthalensis* became attached to the Gibraltar specimen also. A few months ago there came to light in Rhodesia an extraordinary skull, so different from the other types that a new species, *Homo rhodesiensis*, had to be created to receive it. In most respects it was very much more primitive than the Neanderthal type, though the individual specimen suggested that it was more recent in date. But the most remarkable relic of ancient types of man was the Piltdown skull, recovered in Sussex about ten years ago, which threw a clearer light upon the early history of the human family than any other known fossil remains. A new genus of the human family, called *Eoanthropus*, or the "dawn man," was created on the basis of the Piltdown skull; it was more primitive than anything hitherto discovered, except the *Pithecanthropus* or "ape-man" of Java.

The Gibraltar specimen was much flatter than the skull of modern man, the eye sockets much larger, and the nose merged into the face without any distinct line of separation. The Rhodesian skull at first sight presented a striking resemblance to the Gibraltar specimen; the eyebrow ridges were enormous, much larger than in the most primitive type of living man—the Australian aboriginal—and the curve of the nostril resembled that of the gorilla. From the photographs which arrived in this country before the skull itself it appeared to be very like the *Pithecanthropus*, but an examination of the actual skull showed it to be much more modern than the Javan specimen. The Heidelberg jaw, discovered in 1907, which presented a close approximation to the ape, but had typical human teeth not much bigger than those of modern man, was 3 mm. too short and about the same distance too narrow to fit the Rhodesian skull, which therefore corresponded to a face of quite phenomenal proportions. There had been a good deal of discussion in the medical journals as to the meaning of two holes found in the Rhodesian skull, and it was suggested that the individual had suffered from mastoid disease. It was, however, impossible to attribute these holes to any such pathological condition. He had examined fifteen or twenty skulls of Egyptians of the pre-dynastic period—at least sixty centuries old—who suffered and died as a result of mastoid disease, and the lines of inflammation running along between the muscular planes marked out distinctly the way in which the disease had spread. In the Rhodesian skull there was no trace of any such inflammatory reaction. The holes were more consistent with the theory of the gnawing of beetles. The teeth of the Rhodesian man were affected by true caries, precisely of the modern type, whereas in pre-dynastic skulls from Egypt caries was practically unknown. The lecturer added some other details of the Rhodesian skull which he gave in a former lecture on a similar occasion (BRITISH MEDICAL JOURNAL, February 4th, 1922, p. 197).

The relative position of these different species and genera in the human family was next considered. The most primitive was represented by the Javan skull, above which stage the genus *Homo* separated, and three specimens of this genus were now known, including *Homo sapiens*, to which all the living members of the human family belonged. A great deal of controversy had taken place with regard to the Piltdown remains, and all foreign anthropologists appeared to assume that the Piltdown jaw was simian. Apart from the inherent unlikelihood that the jaw of a hitherto unknown type of chimpanzee should have been found within the same yard of earth as the skull, minus the jaw, of a hitherto unknown type of human being, an independent reconstruction of the skull, which had been made recently in his own department at University College by Professor Hunter of Sydney, proved that the skull harmonized perfectly well with the jaw. The skull presented a form absolutely unknown in any other member of the human family; although it had contained a brain of definitely human capacity yet it reproduced the form of an anthropoid ape, but the skull and jaw had now been harmonized, and there was no doubt whatever that the Piltdown fragments belonged, not to different creatures, but to one individual, the most primitive human with the exception of the *Pithecanthropus* of Java.

An x-ray photograph of the Pittdown jaw showed that the teeth were not typical of the chimpanzee, the pulp cavities were very large, and the walls comparatively thin, whereas in the chimpanzee the pulp cavities were smaller and the teeth much thicker.

The great interest of these fossil remains was that they enabled moulds of the interior of the skull to be made whereby the proportions of the different parts of the brain could be studied. Since the time of Charles Darwin, who himself made no such mistake, everyone who had discussed human evolution had overlooked the organ which was distinctive of the human family, for if there was one thing characteristic of the human being it was his intellectual powers. A study of the endocranial cast of the *Pithecanthropus* showed that the front part of the brain looked as though it had been cramped or hindered in its growth. The same was true of the Rhodesian skull. All those skulls showed a deficiency of the high-domed forehead which characterized modern man. With the development of the human family there was a gradual expansion of the brain. The peculiarities of the human brain represented simply the culmination of a series of processes which began in the Eocene period. The apes and other creatures were not so much phases in the development of man's condition as specialized members of the order *Primates*, which had fallen out of the race and had adopted some specialization of habit and structure to save them from extinction. Man represented that particular group of animals which had not taken refuge in these specializations, but retained all the plasticity and the generalized structure which made it possible for him to take advantage of the opportunity to serve higher purposes when his brain had grown to a sufficient stage.

The lecturer sketched the rise of a particular group of arboreal animals, among whom the most primitive sense of smell first became less important and dominating, while that of sight came to be cultivated. The cultivation of vision led also to the cultivation of the powers of touch and of the motor region. Animals which began to trust to vision received an enormous stimulus to the growth of the cerebral cortex. With the vision becoming convergent the creature was able to guide its paws or hands in the performance of skilled movements; the auditory region also was enhanced in importance, and more significant still was the development of that part of the brain injury to which in the modern brain produced certain definite disturbances of speech. One of the distinctive powers which marked the transformation from the ape to the human being was that of communication by something more than merely emotional cries. The brain of the gorilla as compared with the human brain was singularly deficient in the pre-frontal region, the parietal region, and the temporal area. The expansion which converted the brain of the ape into the brain of the human centred chiefly in these three regions. It was also worthy of note that the part of the brain which developed latest in the human child was the part which was least well developed in the primitive members of the human family. He referred in this connexion to the recent work of Dr. Henry Head on the subject of aphasia and speech disturbances which threw an instructive light on these deficiencies. It suggested that in the Rhodesian brain the power of connected thought and speech had been acquired to some extent, much less so in the case of the Pittdown man and the *Pithecanthropus*.

The last type of development was the expansion of the pre-frontal region, which presumably indicated mental concentration, and the development of the upper part of the brain, which indicated an increased appreciation of the texture and form of objects, probably associated with the skilled movements of the hands. During the last fifty years it had been frequently discussed whether the assumption of the erect attitude and the freeing of the hands might not have been the responsible factor in bringing about the development of man. But the erect attitude had not been assumed in the most primitive members of the human family. Man became erect only after he became a human being. It was one of the results of the new powers associated with the growing brain. The lecturer concluded with a diagram showing the inclination of the medulla oblongata in the subcerebral plane, which was least acute in the gorilla, more so in the *Eoanthropus*, still more in *Homo rhodesiensis*, and at almost the same inclination in *Homo neanderthalensis*, and most acute in *Homo sapiens*. This showed in another way that the assumption of the erect attitude occurred within the human family itself, after members of definitely human rank had come into existence.

The lecture was illustrated by a series of transverse sections of endocranial casts to show the initial broadening of the primitive human brain and the lateness of the acquisition

of the high-domed forehead; also a series of left halves of endocranial casts to demonstrate the process of expansion of the human brain in its phylogeny. This process was shown to include localized expansion of the posterior temporal area, growth of the inferior parietal area, beginning of superior parietal growth, progressive expansion of pre-frontal area, and sudden expansion of inferior temporal area.

On the motion of Dr. SINGER, Professor Elliot Smith was warmly thanked for a lecture which kept the attention of the large audience until within an hour of midnight.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE thirteenth annual meeting of the Oxford Ophthalmological Congress was held at Oxford on July 6th, 7th, and 8th. As in past years, the proceedings took place in the Department of Human Anatomy of the University Museum, kindly lent for the purpose by Professor Arthur Thomson, Professor of Human Anatomy, whilst Keble College was again available as headquarters through the courtesy of its Warden, the Rev. B. J. Kidd, D.D.

The meeting opened at 10.15 a.m. on Thursday, July 6th, with the Deputy Master, Mr. P. H. ADAMS of Oxford, in the chair. In declaring the Congress open Mr. Adams voiced the feelings of all present in expressing deep regret at the absence of the Master, Mr. Sydney Stephenson.

A discussion on "The significance of retinal haemorrhages" was opened by Dr. C. O. HAWTHORNE (London) from the point of view of the physician, and by Mr. P. H. ADAMS from that of the ophthalmologist. The two papers were followed with much interest and the subject was discussed by the following: Mr. ERNEST CLARKE (London), Dr. T. HARRISON BUTLER (Leamington Spa), Dr. LUNDGAARD (Copenhagen), Mr. R. FOSTER MOORE (London), Dr. A. G. GIBSON (Oxford), Mr. N. C. RIDLEY (Leicester), Mr. J. JAMESON EVANS (Birmingham), Mr. D. LEIGHTON DAVIES (Cardiff), Miss MARION GILCHRIST (Glasgow), Dr. STOBIE (Oxford), Mr. MATHESON MACKAY (Hull), Dr. THOMSON HENDERSON (Nottingham), Mr. JOHN HERN (Darlington), Mr. B. CRIDLAND (Wolverhampton), Mr. TRAQUAIR (Edinburgh), and Mr. J. GRAY CLEGG (Manchester).

At the conclusion of the discussion the Annual General Meeting was held, when a resolution of regret at the absence of the Master was unanimously passed. The HONORARY SECRETARY reported that the finances of the Congress were in a satisfactory state, and it had therefore been decided by the Council to make a second donation of ten guineas to the Illustration Fund of the Ophthalmological Society of the United Kingdom; that twenty-six new members had been elected during the year; and that as the extension of the meeting to Saturday had proved so successful last year it had been repeated at the present meeting.

After lunch Mr. C. G. RUSS WOOD (Shrewsbury) read a paper on the comparative value of artificial illuminants embodying some valuable original work by him on the subject, and Mr. T. STEWART BARRIE (Glasgow) in a paper entitled "The spontaneous cure of strabismus convergens" drew attention to the diminution and not infrequently the disappearance of squint in children as shown by statistics obtained in school clinics between the ages of 5 and 14. Discussion followed both papers. The afternoon session concluded with a contribution by Mr. J. GRAY CLEGG (Manchester) in which he gave his impressions of an International Congress of Ophthalmology held in Washington, D.C., U.S.A., in April last, together with interesting experiences of various clinical centres in the United States and Canada.

On Friday morning the Doyne Memorial Lecture was delivered by Dr. J. BURDON-COOPER of Bath, the subject being "The etiology of cataract." After a fitting tribute to the late Robert W. Doyne, founder of the Congress, Dr. BURDON-COOPER reviewed the work already published by various authors on the subject, and then described his own research in this field, upon which he has been engaged since 1905. The lecturer was congratulated upon a valuable contribution to the investigation of the causes of cataract in its various forms, and the opinion was expressed that the address should be read with profit and interest by all ophthalmologists. At its conclusion Dr. BURDON-COOPER received the Doyne Memorial Medal of the year. Mr. A. L. WHITEHEAD (Leeds) described some cases of eclipse amblyopia and their after-history; Mr. A. L. MACCALLAN, C.B.E. (Cairo), referred to the

occurrence of trachoma of the lacrymal sac, and a paper on the dry sterilization of instruments by Dr. C. F. BENZEN (Copenhagen) concluded the morning session.

After lunch members assembled at the Oxford Eye Hospital, where Sir ANDERSON CRITCHETT opened a discussion on methods of operating for cataract. In an extremely interesting address he reviewed the operations of the past. Referring to the various procedures in vogue at the present time, he urged eclecticism in operating as being of the first importance; he had advised this as early as 1883 in a paper published in the *BRITISH MEDICAL JOURNAL*, and his subsequent experience up to the present time strongly confirmed this view.

Dr. LUNDGAARD (Copenhagen) described a subconjunctival method of extracting cataract which he had found of good service in a number of cases. Lieut.-Colonel H. SMITH, C.I.E., I.M.S., late of Amritsar, spoke on the intracapsular operation as performed by Dr. Barraquer of Barcelona, and discussed the subject in general. Dr. T. HARRISON BUTLER (Leamington Spa), Mr. C. KILLICK (Bradford), and Mr. B. CRIDLAND (Wolverhampton) referred to the value of cutting a bridge of conjunctiva in making the section, and gave their experience of cases. The subject was further discussed by Mr. E. E. MADDOX (Bournemouth), Mr. JOHNSON TAYLOR (Norwich), and Mr. A. H. H. SINCLAIR (Edinburgh).

On Saturday morning papers were read by Mr. J. GRAY CLERGE (Manchester) on bilateral symmetrical congenital korectopia and melanosis of the eye, skin, and palate; by Mr. A. S. PERCIVAL (Newcastle-on-Tyne) on (1) a note on light sense, (2) a neglected factor in the etiology of coal-miners' nystagmus; by Dr. T. HARRISON BUTLER on "Changes in refraction," a contribution which met with free discussion; and by Mr. A. GREENE (Norwich), who described (1) a useful point in squint operations and (2) a case of foreign body in the lens.

In the Scientific Museum Mr. J. H. TOMLINSON (London) exhibited a transillumination lamp with a rheostat to run from the main, and some interesting pathological specimens were shown by Mr. R. J. COULTER (Newport), Mr. N. PIKE (Chalfenham), and Mr. B. CRIDLAND. In the Commercial Museum a large collection of ophthalmic apparatus and instruments was on view. On Thursday afternoon at the close of the session a garden party was held at New College, where members and their friends were received by Professor Turner and the Hon. Mrs. E. F. Matheson. The annual dinner took place in the evening in the Hall of Keble College.

The meeting was highly successful and well attended, and amongst members from overseas were Dr. Lundsgaard (Copenhagen), Professor Fritz Ask (Lund, Sweden), Dr. C. F. Bentzen (Copenhagen), Dr. Saunte (Odense, Denmark).

England and Wales.

UNIVERSITY OF LIVERPOOL.

At the recent graduation ceremony the degree M.Ch. was conferred on Mr. Thomas H. Bickerton, lecturer in ophthalmology. Mr. Bickerton two years ago retired from the post of ophthalmic surgeon to the Royal Infirmary, and was appointed honorary consulting surgeon. His services of many years' duration to the hospital were signally recognized by the conferment of the honour of President of the Royal Infirmary at its last annual meeting. Mr. C. Thurstan Holland, lecturer in radiology and medical officer in charge of the electrical and orthopaedic department, Royal Infirmary, also received the M.Ch. degree.

MEDICAL AND SURGICAL TEACHING AT LEEDS.

As indicated in recent articles by our Leeds correspondent, an important step has been taken by the University of Leeds with the object of assisting in the further development of the clinical teaching of medicine and surgery. Three new full-time officers have been appointed—one as medical tutor and registrar and two as clinical assistants in surgery. These officers will devote their whole time to teaching and research in the School of Medicine and in the General Infirmary at Leeds. The Council has made the following appointments to the new posts thus created: Dr. W. MacAdam has been appointed medical tutor and registrar; since July, 1919, he has held the appointments of lecturer in pathology at the University of Leeds and assistant pathologist to the Leeds

General Infirmary. He has made a number of contributions to medical literature. Mr. H. W. Symonds has been appointed clinical assistant in surgery; he was made resident surgeon-officer at the General Infirmary in March, 1919, and part-time demonstrator in anatomy at the Leeds Medical School in January, 1921. He holds appointment at present as surgical specialist to the Ministry of Pensions, and has a commission as major in the Second Northern Casualty Clearing Station. Mr. P. J. Moir has been appointed clinical assistant in surgery; since 1920 has acted as house-surgeon, resident casualty officer, and resident surgical officer at the Leeds General Infirmary.

TUBERCULOSIS ADMINISTRATION.

Circular 304 (England), addressed by the Minister of Health to tuberculosis authorities, deals with the procedure for securing adequate diagnosis in doubtful cases of tuberculosis. The Ministry of Pensions system of Medical Record cards the length of stay in residential institutions of ex-service cases of tuberculosis (under Memorandum 30/T), and leave of absence from residential institutions in such cases. Under the first head two cases are dealt with, that of the pensioner who is due for re-board in which the diagnosis is considered doubtful by the Ministry of Pensions Commissioner of Medical Services or by the Medical Board, and that of the ex-service man claiming under Article 9 of the Royal Warrant to be suffering from tuberculosis attributable to or aggravated by war service. In both cases the area D.C.M.S. will request the tuberculosis officer to furnish a report on form M.P.M.S.O.122, unless a report has already been furnished on form T.S.15A under Memorandum 30/T. A fee of 5s. is payable for each report on the new form. In the case of form T.S.15A the fee is only payable where attributability to or aggravation from service is finally established. Cases in which the Medical Board considers the evidence for or against the presence of tuberculosis inconclusive are to be referred to an expert officer of the Ministry for a decision. Five such experts have been appointed under the title Deputy Commissioner of Medical Services, Tuberculosis. These officers will be responsible for securing observation of doubtful cases in hospitals under the control of the Ministry of Pensions. In such cases the D.C.M.S.(T.B.) will notify the tuberculosis officer concerned and secure his co-operation in examination and diagnosis and decision as to attributability. Close liaison between the D.C.M.S.(T.B.) and the tuberculosis officers in his region is desired. In connexion with the length of stay of ex-service cases in residential institutions provision is made for the exercise by the D.C.M.S.(T.B.) of the right of the Minister of Pensions to call upon tuberculosis officers for special reports upon patients continuously resident in such institutions for six months or longer. No fee is payable for these reports.

The names and addresses of the D.C.M.S.(T.B.) and the areas for which they act are as follows:

Dr. D. G. M. MUNRO, 55, Lionel Street, Birmingham. Derbyshire, Herefordshire, Leicestershire, Lincolnshire, Northamptonshire, Nottinghamshire, Rutlandshire, Shropshire, Staffordshire, Warwickshire, Worcestershire.

Dr. G. B. PRICE, Burton Court, Chelsea, S.W.3. London, Bedfordshire, Berkshire, Cambridgeshire, Essex, Hertfordshire, Kent, Middlesex, Norfolk, Oxfordshire, Southampton, Suffolk, Surrey, Sussex.

Dr. W. L. LYALL, 122, George Street, Edinburgh. Cumberland, Durham, Northumberland.

Dr. F. WEBB, 76, Newton Street, Manchester. Cheshire, Lancashire, Westmorland, Yorkshire.

Dr. HALLIDAY SUTHERLAND, Clifton Down Buildings, Bristol. Cornwall, Devonshire, Dorsetshire, Gloucestershire, Somersetshire, Wiltshire.

OPENING OF DURHAM COUNTY CONVALESCENT HOME.

On July 1st Durham county celebrated the opening of the E. F. Peile Convalescent Home for nursing mothers and children under the age of 5 within its area. As the name implies, the house was a gift to the Maternity and Child Welfare Committee by the late Mrs. and Miss Fanny and Miss Helen Peile of Greenwood, Shotley Bridge. It was a great disappointment to all their friends that two of the donors were not spared to see the home opened, but their generosity and interest in the mothers and babies have now a permanent testimony. Dr. Ethel Williams, for Miss Helen Peile, declared the home open, and gave a most interesting address. Councillor Hedley Mason, chairman of the Maternity and Child Welfare Committee, presided, and warmly thanked all who had helped to forward the opening of the home.

Other speakers were Dr. T. Eustace Hill, county medical officer, and Dr. Mabel Brodie.

The home is situated in the middle of Shotloy Bridge village. Only mothers actually nursing babies (not over six months old) are admitted. This is to help those finding difficulty in breast feeding or those recovering from illness following confinement. Children suffering from rickets and similar debilitating diseases, who are not hospital cases, will be admitted, provided they can be certified free from infection and non-verminous, for a period of not less than a fortnight. The maintenance fee has been fixed at 25s. for nursing mothers, and 15s. a week for children without their mothers. The staff consists of matron, staff sister, two nursery trained nurses, and as the home is intended to be a training centre for nursery nurses three pupils will be taken. If later on it is thought practicable this number will be increased, and the domestic staff of three correspondingly reduced. The aim is to give at least six months' training to suitable girls over the age of 17, who wish to become children's nurses. They will be taught the general care of children, nursery routine, including all cooking and sewing necessary, the care of the nursing and the expectant mother, the management of breast feeding, etc., and the general principles of kindergarten and elementary child welfare work. It is intended that mothers in residence will also get a training in mothercraft. The senior welfare medical officer has been appointed visiting medical officer, while the medical officer of the Richard Murray Hospital is the medical officer to the home.

There is ample playing space in the grounds for children and shady corners in which the mothers can rest; the kitchen garden is a great asset. On the ground floor are the day nursery and mothers' rest room. Three night nurseries, to which the children will be apportioned according to age, together with the mothers' and the staff bedrooms, are on the first floor. A ward kitchen has been provided by utilizing part of the first floor landing, and isolation accommodation has been arranged in the building communicating with the rear of the building has been furnished as inexpensively as was consistent with the needs and comfort of the patients. Patients are being admitted mainly through the welfare centres, where the medical officers, aided by the health visitors, who have an intimate knowledge of their home conditions, can judge of the suitability of the applications.

Ireland.

IRISH MEDICAL SERVICES.

At a recent meeting of the National Association of Insurance Committees a deputation was appointed to wait upon the Ministry of Health with regard to the unsatisfactory position of the Irish medical services. It was suggested that the housing scheme should not be segregated from any scheme for the treatment and prevention of tuberculosis, especially in rural areas. It was stated that a resolution was recently passed by the Cork Committee urging the Minister of Health that tuberculosis should be notifiable, as an infectious and contagious disease, by all members of the medical profession. It must, however, be borne in mind there has not been so far a Minister of Health appointed in either of the Irish Parliaments. In the northern Parliament a great deal of medical administration is done by the Minister for Labour, and in southern Ireland medical administration is, as heretofore, administered through the Local Government Department. Recommendations were made that in any tuberculosis scheme provision should be made for the detection of the disease in school-going children, and that affected children should be sent to an institution where they could be treated and educated at the same time. Another recommendation made was that schools should be provided with a room where children, who might get wet when going to school, could make a change of garment in order not to stand in wet clothes all day.

A memorandum was submitted by the County Dublin Committee for the consideration of the Association. The document contained the following recommendations, which it will be seen are much on the lines of the Report of the Irish Public Health Council:

- (1) A medical service paid by the State.
- (2) Central administration to be temporarily administered by the Local Government Board.

(3) A health council composed of representatives of local authorities and other bodies.

(4) The county or borough to be the minimum health unit, and a whole-time medical officer of health and veterinary surgeon to be appointed for each unit.

(5) Mandatory legislation on local authorities.

(6) District nurses for county health schemes.

SALARIES FOR POOR LAW MEDICAL OFFICERS.

The County Kildare Health Committee has decided to standardize the salaries for all Poor Law medical officers. In the county dispensary medical officers are to receive a minimal salary of £300 per annum, increasing by annual increments of £10 until a maximal salary of £400 is reached. The scale is made retrospective for existing medical officers. This scale is considered reasonable by the doctors concerned, and they have expressed their appreciation of the desire of the County Kildare Health Committee to treat their medical officials on an equitable basis. The scheme has not yet been sanctioned by the Local Government Department, and the Irish Medical Secretary (Dr. Hennessy) has been asked to wait upon that body in connexion with the question.

Correspondence.

FOETAL WELFARE.

SIR,—The subject of foetal welfare and foetal mortality is to be discussed in the Section of Obstetrics at the Annual Meeting of the British Medical Association in Glasgow, and it would make for considerable progress in this branch of preventive medicine if some definite and practical action were taken as the result of this discussion.

The few years in which the study of ante-natal physiology and pathology has been carried out have established very conclusively the two following points.

I. That there is a vast amount of ante-natal mortality which cannot be estimated by any other method than that of mere guesswork. Until obstetricians urge the necessity for the registration or notification of abortions no reliable information can be obtained as to the enormous wastage of child life. The thorns in the path of the medical practitioner, should such a notification take place, will not be in the violation of a patient's confidence, but in the diagnosis of early specimens of discharged ova. The registration of illegitimate births has not given rise to difficulties, and now that V.D. conditions are liable to notification surely no objection can be put in the way of any honest endeavour to combat the foetal mortality that is known to be so great. Notification of abortions might to a small extent curtail criminal methods of child murder which are so widespread in this country.

II. The further we carry out research upon ante-natal and intra-natal deaths the more are we convinced that a great number of such deaths are easily preventable if we had the means for their prevention at our disposal: such means being the adequate training of students and midwives, and also of post-graduates. All maternity hospitals should have an indoor and outdoor ante-natal or foetal welfare departments, and facilities should be given for the necessary biochemical and bacteriological investigations of ante-natal conditions. For it is mainly in the field of biochemistry that the harvest will be gathered. The life of the child should be cared for from the earliest conception of the ovum, and this attitude towards obstetrical problems will give results far beyond our present imagination, not only in ante-natal treatment but perhaps most of all in the prevention of intra-natal complications and operations. At the present moment the investigation of ante-natal problems is haphazard and uncontrolled by any central authority other than administrative. Workers are blindly seeking information upon reliable methods. Much time is wasted in following up ideas which prove themselves useless and profitless in the end. Sometimes a whole year's work has to be scrapped because a particular biochemical test has been condemned. The whole general teaching of obstetrics is at present chaos, and the public must be educated as to the great necessity for giving financial assistance to this branch of preventive medicine. The Medical Research Council is the first corporate body to give help in foetal welfare research, but what is required is co-ordination among workers.

I would suggest that the Ministry of Health and Medical Research Council be asked to co-operate with a central committee which has as its object the investigation of foetal

welfare, that it should be composed of representatives from the obstetrical societies of Great Britain, infant specialists, medical officers of health, and research workers both in physiology and pathology, and that a scheme should be drawn up for a definite line of research which could be undertaken, and that help and advice should be given as to the method and means of research.

This scheme would be an amplification of the present work of the Medical Research Council, and would bring in those who are engaged in the training of students and midwives and more especially those responsible for the health of the poor, such as medical officers of health.

I venture to make this suggestion as one suitable for discussion at the Annual Meeting in the hope that it may help towards the solution of our present difficult problems with regard to foetal welfare.—I am, etc.,

A. LOUISE McILROY.

Obstetrical and Gynaecological Unit,
Royal Free Hospital, London,
July 17th.

THE SKULL OF SIR THOMAS BROWNE.

SIR,—It may be known to some of your readers that the skull of Sir Thomas Browne has recently been reinterred at Norwich, but that previously it came up to London, where careful measurements, drawings, and tracings of it were made. It is proposed to publish a full account of the skull in *Biometrika*, but it would much add to the interest of the proposed monograph if it were accompanied by a series of reproductions of the portraits and engravings of one of the most noteworthy of Englishmen who have combined the study of medicine with the pursuit of literature. The large number of plates required to illustrate adequately the relation of the skull to the portraits renders—under the present conditions of both printing and illustrative work—the appearance of a complete monograph, such as we desire to see issued, very difficult. We propose, therefore, to issue one hundred copies of the monograph at the price of 1 guinea each, if lovers of Sir Thomas Browne can be found in adequate numbers to subscribe for copies. Will you kindly permit us to appeal through your columns for the names of those who are willing to aid in this scheme for putting on permanent record the physical aspect of the author of the *Religio Medici*, who, by that and his other works, has won a unique position in the heart as well as in the mind of every cultured Englishman? Willingness to subscribe may be notified to either of the undersigned.—We are, etc.,

ARTHUR KEITH,
KARL PEARSON.

London, July 12th.

AORTIC MURMURS.

SIR,—I entirely agree with Dr. Thomas Lindsay that the aortic murmur he has written about recently ought to be more generally recognized to avoid a diagnosis of heart disease being made in healthy subjects by those who are unacquainted with this condition.

He doubts whether the murmur I described in the *Lancet* in 1909 is of the same character as that about which he wrote in the *British Medical Journal* of May 13th last. Having reread both of our descriptions and given them to others to read neither I nor they can see the difference. We both find that the murmur is brought into evidence by raising the arms, as in holding aside the clothes for examination of the chest, and that it disappears when the arms are hanging by the sides. It was for this reason I called it a "postural murmur."—I am, etc.,

E. L. MOSS,
Major, R.A.M.C.

Louise Margaret Hospital, Aldershot, July 6th.

INFECTIVITY OF ARTIFICIAL DENTURES.

SIR,—Dr. D'Oyly Grange is to be congratulated on calling attention to this most important subject (*BRITISH MEDICAL JOURNAL*, July 8th, p. 43). The efficient cleansing of artificial dentures is all too much neglected even by the better educated section of the public.

That this is so is very largely due to the very general omission of the dentist to give detailed instruction and timely criticism. A denture should be removed and brushed preferably after each meal, always after breakfast and at night; the gum covered by the plate, and so deprived of the natural friction of the tongue, and especially the gum margins round remaining teeth, should also be vigorously brushed. Before retiring the denture should be scrubbed with a stiff brush, dipped in water (preferably with a lump of soda added), rubbed on a piece of soap, and then charged with

powder or paste. Special care should be given to the inside of clasps fitting round natural teeth, for which a pointed piece of cane should be used instead of a brush.

During the night the denture should be left in water to which some antiseptic has been added. For this purpose a chlorino preparation is suitable, for, though the taste is unpleasant, its effect, especially on gold, is almost magical, and greatly diminishes the trouble of brushing.

From Dr. D'Oyly Grange's statement that it is sometimes necessary to wear dentures at night I must differ emphatically, and have yet to see the case where it is so. Patients who study their appearance in bed may insist on wearing them, but that is another matter.

The contour of the face naturally suffers while the denture is out, but that is all; and the adhesion of the denture may not be so good immediately on insertion in the morning, but after wearing for a few minutes this is recovered. I regard it as a most pernicious practice.—I am, etc.,

J. H. BADCOCK, L.D.S. and M.R.C.S., L.R.C.P.

London, W., July 11th.

THE INTERSTITIAL GLAND AND SEX PROBLEMS.

SIR,—From the tone of Dr. Rawlings's letter in the *JOURNAL* of July 1st and from other communications I have received personally it would appear that my letter published on June 17th (p. 973) has caused some misunderstanding. The passage in my letter to which exception has been taken was intended merely as a supposition. It is as follows:

"If we are to accept Rumley Dawson's sex theory at all—and, so far as I have been able to ascertain, no later investigations have actually disproved it—then, instead of administering male interstitial gland, as Dr. Williams suggests, in cases of deficient 'maleness,' one would require to administer corpus luteum extracted from the right or male ovary, and from the left or female ovary increases of deficiency in 'femaleness.'"

In the study of sex causation it is impossible to be dogmatic. But if one declines to accept the proffered proof of a theory on the grounds that it is insufficient or unorthodox, it does not necessarily follow that the theory has been "exploded." It requires as many hard facts to explode a theory as it does to prove it. Criticism is ever unduly severe on the unorthodox, and it is this feature that makes Rumley Dawson's work unacceptable to many. The idea of a pair of ovaries possessing heterosexual qualities is against one's conception of Nature, who, as Dr. Williams very neatly expresses it, "does not seem to have evolved dual organs with this kind of end in view."

Certainly Dr. Rawlings's case of a male birth following upon removal of the right ovary in no way disproves the theory of Rumley Dawson, for it is well known that it is impossible to be certain by mere inspection at the time of operation that the whole of the ovarian tissue has been removed. It is also an established fact that the minutest portion of ovarian tissue is sufficient to yield fertilizable ova. Hence the explanation of Dr. Rawlings's case.—I am, etc.,

R. DOUGLAS HOWAT, L.R.C.P. Edin.,

Denholm, Hawick, July 3rd. L.R.C.S. Edin., L.R.F.P.S. Glasg.

CAESAREAN SECTION.

SIR,—In your issue of July 8th Dr. J. H. Martin has claimed priority with regard to certain details of the operation of Caesarean section.

For the past ten years I have been in the habit of turning the uterus inside out to remove placenta and membranes, and also of putting the patient in Fowler's position during convalescence. These practices are not original on my part, because I copied them from other members of the staff who preceded me.

It seems to me that Fowler's position may be applied to any abdominal operation, and that the only person who should receive the credit of it is Fowler himself.—I am, etc.,

AREND. N. McLELLAN, M.B.

Glasgow, July 18th.

SIR,—Mr. S. J. Cameron is apparently inignant about my claim to having introduced (not "discovered") three excellent improvements in this operation at the Royal Maternity Hospital, Glasgow. It is a pity he did not show this indignation at the meeting of the Royal Medico-Chirurgical Society: if he had, then this correspondence would never have taken place.

1. Incision.—Mr. Cameron refers me to his *Manual of Gynaecology*, "published in 1915," when I was in khaki, but gynaecological and general surgical incisions are outwith the

argument; over the Romans went through the right rectus muscle, I have read. I purposely avoided referring to the case where Mr. Cameron severed the veins of the left broad ligament, but in answer to his twitting my comment on this case is that the first time my uterine incision is so far out of place—light good or light bad—as to sever the veins in any broad ligament then I shall cease to perform Caesarean sections.

2. *Turning the Uterus Inside Out.*—Mr. Cameron states that his father, Professor Murdoch Cameron, employed this manoeuvre over thirty years ago. I was house-surgeon to Professor Cameron at the Matorait Hospital for six months in 1909 and assisted him at all his Caesarean sections during that period. On no occasion was the uterus turned inside out, nor was this ever spoken of. As I write I have before me Professor Cameron's article, "Abdominal section as a substitute for the performance of craniotomy" (*BRITISH MEDICAL JOURNAL*, 1891—that is, thirty-one years ago), in which there is no mention of turning the uterus inside out. To avoid much bleeding after the child was extracted he advocates, "place the cut surfaces in apposition and press them tightly together." This was repeated after the placenta had been "extracted." In his third Caesarean he describes the same procedure and apparently it was followed in many others. I have also before me another article by Professor Cameron, published in 1901, where improvements in technique are gone into in detail, but still no mention of this manoeuvre. Totally opposed to turning the uterus inside out is the following sentence: "On no account should the uterine cavity be washed out or medicated in any way; the less the parts are interfered with the better." I leave the matter there.

3. *Sitting Posture.*—Here I can only refer Mr. Cameron to the *Proceedings of the Royal Society of Medicine*—discussion on Caesarean section, 1920—and also to the *Transactions of the Glasgow Obstetrical Society* last year, where I get full credit from one of our seniors—namely, Professor Munro Kerr. Mr. Lennie's contribution is a thin echo of his chief's.—I am, etc.,

Glasgow, July 15th.

JAMES H. MARTIN, M.D.

Sir,—I notice in the *BRITISH MEDICAL JOURNAL* of July 8th, amongst the correspondence, that Dr. Martin of Glasgow takes exception to the technique as described by Mr. S. J. Cameron in reporting his cases of Caesarean section in your issue of June 10th. I cannot allow this to go unchallenged, as Mr. Cameron carried out the methods described in his paper—namely, (1) the abdominal incision through the right rectus, (2) turning the uterus inside out to remove the placenta and membranes, and (3) turning the patients in the Fowler position—ever since his apprenticeship as operative surgeon at the County Maternity Hospital, Bellshill, a considerable time before the date of Mr. Martin's paper of January, 1921.—I am, etc.,

July 11th.

H. J. THOMSON,
Medical Superintendent,
County Maternity Hospital, Bellshill.

Sir,—It is with considerable astonishment that I read a letter in your issue of July 8th from Dr. Jas. H. Martin, which implies that it was only after Dr. Martin's paper on Caesarean section was read to the Glasgow Royal Medico-Chirurgical Society in April, 1921, that Dr. Cameron followed the technique mentioned.

I had the honour to be Dr. Cameron's house-surgeon at the Glasgow Royal Maternity and Women's Hospital from November, 1920, to April, 1921, and the technique which he then employed and had followed for several months in all straightforward cases of Caesarean section was the same as that described in Dr. Cameron's paper which appeared in the *BRITISH MEDICAL JOURNAL* of June 10th—namely, the incision through the right rectus sheath, the turning inside out of the uterus for the removal of the placenta, etc., and the putting of the patient in Fowler's position after the operation.

While attending Professor Murdoch Cameron's clinic as a student I had also seen the uterus inverted as mentioned above.—I am, etc.,

Glasgow, July 11th.

ALISON M. HUNTER, M.B., Ch.B.

Sir,—Dr. J. H. Martin in his letter published in the *BRITISH MEDICAL JOURNAL* of July 8th, 1922, claims to have introduced certain modifications in the technique of Caesarean section. Further, he couples with his assertion of priority

the insinuation that Dr. S. Cameron, after hearing Dr. Martin's paper, has adopted the improvements detailed, and has recently published an account of this technique without recognition of its originator. Such a suggestion is entirely misleading.

As house-surgeon in the Western Infirmary in 1918, in the Maternity Hospital in 1919, and subsequently as assistant-surgeon in the latter institution, I have had ample opportunity of learning Dr. Cameron's operative methods. Ever since I have been associated with him it has been Dr. Cameron's constant practice to open the abdomen through the right rectus sheath, and a considerable period before Dr. Martin delivered his paper (April 1st, 1921) Dr. Cameron was in the habit of turning house-surgeon and students of the special danger of making the incision on the left side in cases of Caesarean section. To facilitate the removal of placenta and membranes the expedient of turning the uterus inside out was regularly employed by him, and in this he was not unique. As house-surgeon I never heard anyone remark on this procedure as of recent introduction; it was accepted, indeed, without comment as a well-recognized manipulation. Dr. Cameron's patients were nursed in Fowler's position as a routine, but this attitude was not strictly enforced. On the contrary, the women were allowed to assume any posture they might prefer as more comfortable.

In justice to Dr. Cameron I consider myself bound to communicate these facts.—I am, etc.,

J. HEWITT.

Research Department, Glasgow Maternity
Hospital, July 12th.

Universities and Colleges.

UNIVERSITY OF LONDON.

MR. DANIEL T. HARRIS has been recognized as a teacher of physiology at University College, and Mr. J. H. Woodger, B.Sc., is appointed to the University Readership in Biology tenable at Middlesex Hospital Medical School.

Professor E. H. Starling, M.D., F.R.S., has been added to the Board of Examiners in Psychology for the B.A. and B.Sc. examinations in 1922.

Certain changes have been made in the constitution and powers of the Boards of the Faculties of Arts, Medicine, and Science. The changes in detail include: (1) That, whereas the existing boards can only report through their respective faculties, thereby often causing considerable delay, in future the boards will report direct to the referring body; and (2) that the secretary of each board will not, as heretofore, be a member of the board, but a member of the administrative staff appointed by the Principal Officer. The changes do not affect in any way the statutory powers of the boards of studies or of the faculties.

The following examiners for the examination for the diploma in Psychological Medicine were reappointed for the session 1922-23: For Part A (i) and Part B (i), Sir Frederick Mott and Dr. E. Farquhar Buzzard; for Part A (ii) and Part B (ii), Dr. W. H. B. Stoddart and Dr. R. H. Cole.

Mr. H. L. Eason, C.B., C.M.G., M.D., M.S., and Sir Sydney Russell-Wells have been appointed chairmen of the Academic Council and Commerce Degree Committee respectively.

The following have been appointed associate examiners for the M.B., B.S. Examination for the session 1922-23:—*Medicine*: Dr. C. Boltou, Dr. W. P. S. Brauson, Sir Charlton Briscoe, and Dr. C. Wall. *Surgery*: Mr. C. G. Choyce, Mr. H. S. Clegg, Mr. W. S. Handley, and Mr. T. P. Legg. *Midwifery*: Mr. J. S. Fairbairn and Dr. Eardley Hollaud. *Pathology*: Mr. T. W. P. Lawrence and Mr. B. H. Spilsbury.

Clause 1 of the regulations for the Gilchrist scholarship for women has been amended as follows:

Candidates must have passed an intermediate examination or the first examination for medical degrees of the University: a candidate who has completed her twentieth year on or before June 14th in the year of the scholarship examination for which she enters will be disqualified if she has passed an intermediate examination or the first examination for medical degrees earlier than June of the previous year.

The regulations for the Gilchrist studentship for women have been amended by the addition of the following:

The selected candidate will be required to devote her whole time to her studies during her tenure of studentship.

In its annual report the Committee of Management of the Brown Animal Sanatory Institution states that 5,700 animals were brought to the institution during the year 1921. Recent advances on the biology of bacteria was the subject selected for the five lectures delivered by the Superintendent at the Royal College of Surgeons in December, 1921, as required under the will of the late Mr. Brown. The superintendent, Mr. F. W. Twort, continued his work on influenza and on filter-passing lysins which are associated with and which dissolve up bacteria. He has also carried out some work on the ultra microscopic viruses on dysentery and on leprosy. Mr. Twort's appointment as superintendent of the institution has been continued for one year from June 1st, 1922.

Applications for the William Julius Mickie Fellowship, value of at least £200, must reach the Principal Officer of the University not later than the first post on October 2nd. It is awarded

nnnnally by the Senate to the man or woman who, being resident in London and a graduate of the University, has in its opinion done most to advance medical art or science within the preceding five years, and has therein shown conspicuous merit.

UNIVERSITY OF BRISTOL.

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—Part II (Completing Examination): J. R. Duerton, Part I (including Forensic Medicine and Toxicology): Georgina R. Dunn, Idris Williams. Part I only: Mariel V. Joseelyno, Dorothy Staley, F. K. Wilson.
D.P.H.—J. B. Adams, R. D. Davies. Part II (Completing Examination): B. A. Astley-Weston. Part I only: F. P. Mackle.

UNIVERSITY OF MANCHESTER.

The following candidates have been approved at the examination indicated:

D.P.H.—Martha F. Barritt, F. da Cunha, Winifred I. Doherty, Florence M. L. Graham, T. H. Jones, W. H. Leigh, J. K. Land, G. H. Roberts, Doris A. Taylor, Mary I. Turner, Frances G. Willocks.

The following awards have been made:

Tom Jones Memorial Surgical Scholarship, Eric A. Linnell. Dauntsey Medical Scholarship, (1) Maurice Sheehan, (2) Kathleen Sheehan. University Prize in Medicine, divided between R. L. Holt, F. H. Smirk. Dunsaville Surgical Prize, Hilda Pratt. Sidney Renshaw Prize, F. H. Smirk.

UNIVERSITY OF EDINBURGH.

The following candidates have passed the final examination for the Diploma in Public Health: G. G. Allan, Dora W. Gerrard, Mary H. M. Gordon, Margaret Gray, Helen R. T. Hood, J. S. Mcnebeth, Agnes B. Macgregor, Florence E. McKenzie, Janetia J. Powrie, Margaret M. Prondfoot, G. Stewart, J. D. Stewart.

UNIVERSITY OF ABERDEEN.

At the graduation ceremony on July 13th the following degrees and diplomas were conferred:

M.D.—John Smith, Charles Clyno.
CH.M.—A. V. R. Dou.
M.B., CH.B.—W. L. Hector, H. R. N. Ironside, H. R. S. Crniekshank, H. A. N. Gordon, Gladys N. Watson, Isabella A. Baxter, A. F. J. Buchanan, Janet Coghill, Margaret J. Duncan, R. J. Nes, Winifred M. Aulio M. Jack.
J. B. Jessiman, J. C. Kerrin, F. H. Lakin, W. Lawie, N. H. Leslie, G. L. McCulloch, G. A. Macdonald, Isabella F. Mackenzie, W. McC. R. B. Milno, A. A. Mel, old, C. E. Riddell, C. J. Stephen, R. Thomson, West.

D.F.

* Honours for Thesis.
† First Class Honours.
‡ Second Class Honours.
§ Completed Final Medical Professional Examination with distinction.
|| Completed Final Medical Professional Examination with much distinction.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

The following candidates have been approved at the examinations indicated:

FINAL M.B., PART I.—Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Pathology and Bacteriology: J. E. Elias, R. A. D. Pope, M. Cohen, J. J. O'Grady, J. K. S. Thompson, J. M. Mounsey, R. A. Dench, G. Robinson, O. G. Wilde, C. W. J. Ingham, J. A. du Toit, L. D. Dennard, L. E. J. Warner, C. B. McQuillan, R. W. Tarnock, Sylvia B. Wigoder, J. M. Gordon, C. B. Huron, J. Kalmans, Eashy, M. D. Fox, J. McAuliffe, Alice E. Dorothy I. Henry, Bacteriology only: W. L. W. Smith, & Therapeutics, Medical Jurisprudence and Hygiene: S. McDermott, Gladys Weatherill, A. V. B. Crawford, J. L. Stuart. Materia Medica and Therapeutics only: E. C. Downer. Medical Jurisprudence and Hygiene only: Eileen Brangan.
PART II.—Medicine: J. Cornick, M. G. J. Powell, J. V. Carroll, M. Sayers, Beryl F. E. Coekle, M. P. Lowy, D. J. Malan, G. S. Moran, J. H. I. S. W. Russell, J. D. Wight, G. Weldon, J. M. O'Connor, Midwifery: J. C. Earl, Anna, L. J. Coetzee, R. Linman, P. Samolsky, Maria E. J. Lait, J. E. McCormick, J. D. Wight, W. R. Burns, J. G. Russell, J. H. Raneb, A. W. F. H. Wagner, C. G. S. Van Heyningen, Van Staden, Alice M. A. Downing, Surgery: M. Bewley, N. McI. Falkner, S. G. Rainsford, J. C. Gillespie, M. M. Viljoen, J. C. J. McEntee, S. W. Russell, Minnie Alper, J. Lait, G. Bewley, R. Hezy, G. Blackall, B. Vivier, M. P. Louw, W. B. E. McCrea, R. N. Perrott, J. V. Carroll, A. E. Drotke, May E. Powell, Florino I. Irwin, J. R. Craig, J. Harte, J. E.

1. Physics, and Meteorology:

2. Sanitary Report, Hygiene and Public Health Law: S. Smith, J. S. Dockrill.

A. V. Dowse.

* Passed on high marks.

QUEEN'S UNIVERSITY OF BELFAST.

At the graduation ceremony held on July 11th the following degrees were conferred:

L.L.D. (Hon. Causd).—Professor J. Lorrain Smith.
M.D.—W. Bryars, F. Campbell, W. Harvey (with gold medal), B. Lyons, F. MacSorley, J. P. Martin, S. Millar (with commendation).
M.Cr.—H. B. Steen (with commendation).
M.B., CH.B., B.A.O.—Isabel E. Bsmford, *C. A. Calvert, *W. Carson, *Olivo M. Darling, *W. G. Frackleton, *Ellen McC. Jackson, *J. F. Knox, *W. Lennon, *R. H. Longmoor, *J. J. McSorley, *R. A. Reid, *R. V. Robinson, *R. Thompson, A. Brown, W. F. Bryson, J. Campbell, J. Carrey, Winifred M. Chambers, W. B. S. Crawford, W. E. Crosbie, W. M. Farr, F. J. Ferguson, E. R. Frizelle, E. V. Greaves, T. V. Griffith, F. Halliday, J. W. Heney, J. Houston, R. Huey, Mary M. Hughes, R. Johnston, Mary J. S. Killen, Ida M. Kirker, A. W. J. Knox, T. Law, M. F. Leslie, J. C. Iston, Emily M. McCandless, H. J. McCavann, W. McConch, N. McKibben, Evelyn M. McKinney, Maude W. McKnight, C. McShane, H. T. McWilliams, J. E. McWilliam, Margaretta McI. Macmillan, J. A. Moody, J. W. Nesbitt, Mary E. Patterson, J. Scott, A. C. Seymour, P. J. Shankey, Elizabeth G. Shillington, G. T. F. Stowey, S. E. Smyth, R. Watson, A. R. Wheeler, J. B. White, Mary A. White, A. A. Woods.

* Second class honours.

D.P.H.—Mary I. Adams, Frances E. Bell, S. McI. Bolton, C. L. Brownhead, J. S. Dudgeon, R. A. Elliott, Winifred E. Hadden, D. Jamison, J. McKay, S. E. Picken, Margaret W. Snodgrass, J. A. Smyth, H. Stewart, W. Tyrrell.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on July 13th. The President announced the result of the election to the Council (see BRITISH MEDICAL JOURNAL, July 15th, p. 112).

Licences and Diplomas.

Licences in Dental Surgery were granted to sixty-four candidates found qualified at the recent examinations.

Diplomas in Public Health were granted jointly with the College of Physicians to twenty-five candidates recently found qualified.

The Diploma in Psychological Medicine was granted to one candidate jointly with the Royal College of Physicians.

A certificate of the Diploma of "F.R.C.S. (with Ophthalmology)" was granted to one candidate.

International Congress of Otolary.

Sir St. Clair Thomson and Mr. Arthur Chentle were appointed delegates to represent the Council at the tenth International Congress of Otolary which is being held in Paris this week.

Alterations in the Rules Relating to College Triennial Prize and John Hunter Medal.

1. The John Hunter Medal excented in bronze shall be awarded with the Triennial Prize of £50.

2. The recommendation for the award shall be entrusted to a committee, which shall consist of three Members of the Council, in addition to the President and Vice-Presidents, to be elected triennially at the quarterly meeting of the Council in the July preceding the year of award.

3. The award may be made triennially by the Council to a Fellow or Member of the College, not on the Council, who has, during the preceding ten years, done such work in Anatomy, Physiology, Histology, Embryology, or Pathological Anatomy, as in the opinion of the Committee deserves special recognition.

4. The Committee shall report its recommendation to the Council not later than the quarterly Council in April subsequent to the expiration of the triennial period.

5. Should no work by a Fellow or Member of the College in the subjects selected be held by the Committee to be deserving of special recognition the Committee shall report to the Council accordingly.

Election of Officers and Lecturers.

Sir Anthony Bowlby was re-elected President, Sir D'Arcy Power was appointed Senior Vice-President, Sir Berkeley Moynihan was appointed Junior Vice-President, and the following appointments were made:

Pathological Curator, Mr. S. G. Shattock; Assistant Pathological Curator, Mr. C. F. Beadles; Pathological Assistant, Mr. C. D. Shattock; Mr. R. H. Burns; Honorary Curator of the Odontological Collection.

Sir Arthur Keith: Six lectures on "Man's position." R. Lawford Knaggs: One lecture on "Remote effects of gunshot wounds of the head." E. M. Woodman: One lecture on "Malignant disease of the upper jaw, with special reference to operative technique." C. A. Joll: One lecture on "The metastatic tumours of bone."

Erasmus Wilson Lecturer.—James Alane Coupland: One lecture on "Observations on the human and comparative anatomy of the parathyroid gland, with investigation of its function and relation to post-operative tetany and the surgical technique its presence demands in thyroid surgery." E. M. Woodman: One lecture on "Lymphatic flow from the gastric and duodenal ulcers and other forms of the hepatic biliary ducts, and their surgical significance."

Arnott Demonstrator.—Sir Arthur Keith: Six demonstrations on the contents of the museum.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At their meeting on July 14th the President and Fellows of the College accepted the resignation of Dr. Thomas Mather Thomson of London, of his Fellowship to which he was elected on April 1st 1921.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates have passed the examination of this school at the termination of the sixty-ninth session—April-July, 1922:

"Dr. S. M. Vassallo ('Duncan' medal), 'Squad-Leader G. S. Marshall, Dr. J. D. Kellersberger, Dr. H. S. Lucraft, Dr. L. M. Moody, Miss C. Shepherd, Dr. O. Teague, Dr. H. Schwartz, Dr. H. C. Kerio, Indian Medical Dept., Major K. G. Ghauraney, I.M.S., Dr. V. Nath, Miss M. Young, Lieut.-Colonel S. Hunt, I.M.S., Captain B. F. Beeson, I.M.S., Dr. C. Dunscombe, Dr. T. M. M. Horsfall, Dr. N. L. Varma, Dr. P. Gupta, Major F. C. Barker, I.M.S., Captain H. J. M. Chruszczek, I.M.S., Dr. D. I. Cameron, Miss N. B. Henkley, Dr. A. T. Euriyan, Dr. M. Theller, Dr. A. B. Cottrell, Dr. G. E. Peacock, Miss J. Cave, Dr. K. N. Choksy, Mrs. L. M. Cottrell, Dr. J. L. Gregory, Dr. J. Jones, Miss M. Norris, Dr. N. V. Pandit, Dr. W. M. A. Rabinan, Dr. J. Loudon, Miss M. Murphy, Dr. W. W. Wood, Miss E. O'Keefe, Dr. Y. Maximos, Dr. A. H. Tawfik.

* With distinction.

Errata.

In the list of successful candidates for the M.B., Ch.B. degrees of the University of Liverpool published last week (p. 111), it should have been indicated that Mr. H. Cohen received first-class honours with distinction in medicine in addition to surgery and obstetrics.

In the University of Edinburgh pass list, also published last week, on p. 111 an asterisk should have been attached to Mr. W. R. Levio's name to intimate that he had passed with distinction.

Obituary.

ARCHIBALD LANG McLEAN, M.D.,

Late Captain A.A.M.C.

Our Special Correspondent in Sydney writes: Archibald Lang McLean, who took a prominent place in the great war, and was also medical officer in the Mawson expedition to the South Pole, died in the Royal Prince Alfred Hospital, Sydney, in his 38th year. He was a native of Sydney, and was educated at the Sydney University, where he graduated B.A. with honours in 1906, and M.B., Ch.M. in 1910. After leaving the university he was a resident medical officer at the Lewisham Hospital, and subsequently at the Coast Hospital. He was chosen by Sir Douglas Mawson to accompany his Antarctic expedition as surgeon in charge and bacteriologist for one year, but at the request of Captain Davis he remained a second year. At the outbreak of war he was in England, and soon joined the R.A.M.C. While in France he served with the 13th General Hospital and the 20th Casualty Clearing Station, but was invalided to England in consequence of a poisoned finger. He was then discharged and returned to Australia.

In September, 1917, he joined the A.A.M.C. as captain. During the nine months he was waiting to be sent overseas he obtained the M.D. with the University Prize Medal. He accompanied the A.I.F. to Egypt and France, where he was attached to the 17th Battalion and the 5th Field Ambulance, and while serving in this capacity was twice gassed. He received the Military Cross for gallantry and devotion to duty, the official account stating that—

"During the attack on August 8th, 1918, of Villers Bretonneux, near Amiens, he followed the attacking troops with his section, tending and dressing wounded under fire on the way. Almost immediately after their objective had been taken he established his first-aid post in the village of Warfusé, where he worked continuously under great difficulties with great courage. Later during the advance on the following day, he established his first-aid post almost on the jumping-off line, where he tended and cared for the wounded under heavy artillery fire. His effort during the whole operation has been beyond praise, and had it not been for his tireless attention a large accumulation of wounded would have occurred. His bravery and devotion to duty was most conspicuous."

After his return from the war he was appointed medical officer in charge of the Red Cross farm colony at Beelbagera. He was editor and collaborator with Sir Douglas Mawson in the production of the *Home of the Blizzard*, and was author of a volume of bacteriological and other researches published by the New South Wales Government printing office in 1919.

The death is reported of Dr. MATTHEW ARDEN MESSITER of Dudley. He was the son of the Rev. G. M. Messiter of Repton, and received his medical education at Queen's College, Birmingham. He took the diplomas of M.R.C.S. in 1873 and L.S.A. in 1874. He joined the late Dr. Houghton in practice at Dudley in the seventies, and early became one of the honorary surgeons of the Guest Hospital, in which institution he took great interest. He was justice of the peace for the county of Worcester, an ex-president of the Birmingham Branch of the British Medical Association and of the Medical Defence Union. Dr. Messiter took great interest in local charities. He leaves a widow and five sons, one of

whom is a member of the medical profession, and another is rector of Kingswinford. At the borough police-court, on July 8th, the chairman referred to Dr. Messiter's work on the bench, and expressed the sympathy and regret of the justices.

Medical News.

THE Fellowship of Medicine and Post-Graduate Medical Association will hold a further two weeks' special course in general medicine from Monday, September 11th, to Friday, September 22nd. A morning and afternoon session will be held each day, and the following subjects will be dealt with: Pulmonary disease, including the x-ray aspect; cardiology; neurology and mental disease; pathology; medical ophthalmology, etc. Copies of the preliminary syllabus with further details can be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W.1.

A MEMORANDUM by the Ministry of Health (65/M.C.W.) indicates the Minister's present requirements as regards the qualifications and duties of health visitors, and calls attention to a modification in the Board of Education (Health Visitors' Training) Regulations, 1919, extending approval to courses of less than a year's duration in the case of nurses with specified training. Points of interest in the memorandum are: the provision for dispensing for the present with the prescribed qualification in the case of health visitors with previous efficient service; a suggestion for reducing the number of inspectors who may visit a given home, and minimizing travelling by combining kindred functions with those of the health visitor, and the statement that the inspection of midwives, often carried out by health visitors acting under the M.O.H., should be under the direct supervision of a medical practitioner, preferably a medical woman. The Health Visitors (London) Order, 1909, will be rescinded as from January 1st, 1923.

Dr. ERIC PRITCHARD has been appointed Consulting Physician to the Queen's Hospital for Children on his retirement from the active staff to take up the post of Medical Director of the Infants' Hospital.

IT was announced last week that the grand total so far received in response to the Combined Appeal for the Hospitals of London is now more than £260,000. This sum includes £50,000 contributed to the Mauston House Fund.

THE annual meeting of the Canadian Medical Association was held at Winnipeg from June 20th to June 23rd, under the presidency of Dr. Edward W. Montgomery. The following officers were elected for the ensuing year: President, Dr. David H. Aruott, London, Ont.; vice-president, Dr. Walter L. Muir, Halifax, N.S.; and secretary, Dr. John W. Seane, Montreal, Que.

IN the list of persons recently made magistrates for the County of Glamorgan are the names of five medical men—namely, Dr. Le Cronier Lancaster, Swansea; Dr. Henry Davies, Abergwynfi; Dr. Hubert Leigh, Treharris; Dr. E. Parry Evans, Llantwit Yardre; Dr. Arthur T. Jones, Mountain Ash.

Mr. SYDNEY DUNSTAN, who for sixteen years has had charge of the dispensary and stores department of the Royal Victoria Infirmary, Newcastle-on-Tyne, has been appointed House Governor and Secretary to that institution in succession to Mr. R. H. P. Orde, who has resigned.

A NATIONAL milk conference will be held on October 16th, 17th, and 18th next in the Guildhall, London. A number of papers on the production of clean milk will be read; there will be discussions on contagious abortion, introduced by Sir Stewart Stockman, and on bovine tuberculosis and tuberculin tests, by Dr. Stanley Griffith and Dr. S. R. Douglas, F.R.S., respectively.

UNDER the will of the late Mr. Daniel Clark, of Cheltenham, the following bequests are made: £5,000 each to the Cheltenham General Hospital and the Leeds General Hospital, £2,000 to the Hospital for Poor Patients, Harrogate, £1,000 each to Dr. Barnardo's Homes and St. Dunstan's Hostel. The residue of the estate, which it is expected will exceed £20,000, will be equally divided between the following hospitals: St. Bartholomew's, Guy's, London, St. Thomas's, St. George's, King's College, University College, Charing Cross, St. Mary's, and Middlesex.

MESSRS. H. K. LEWIS AND CO., LTD., medical publishers and booksellers, of 136, Gower Street, London, W.C.1, have issued a small catalogue of the works on medicine and allied subjects sold by them. The books are grouped under subject headings.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Ailology*, Westrand, London: telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London: telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London: telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin (telegrams: *Pacifilis*, Dublin); telephone, 4737, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

"PASTOR" asks for particulars of Bordighera, N. Italy, as a suitable climate for a nasal or chest case during winter months.

INCOME TAX.

"CYPHER" has had to employ an accountant to conduct his income tax appeal after preparing accounts for him. He asks if he can regard the accountant's fee as a professional expense for income tax purposes.

* * * Yes—such expenses are properly allowed.

"CALEDONIA" wishes to know whether income earned under the Highlands and Islands Medical Service Board, varying according to services rendered, may be returned under Schedule D.

* * * Yes; they may be included in one sum with the earnings of a general practice. Schedule D assessment, however, would probably be refused if the appointment in question were a whole-time one or nearly so.

"W. S. W." purchased in April, 1919, a 14-h.p. 1914 Austin touring car for £475; in August, 1921, he sold it for £230, replacing it with a new 20-h.p. Austin Coupé, price £850.

* * * The difficulty is to ascertain what would have been the cost in August, 1921, of a car similar in condition, quality, and power to that purchased originally. The approximate cost may be calculated as follows, £x being the original—that is, new cost—of a 14-h.p. Austin touring car in April, 1919:

Estimated cost of 14-h.p. car in 1921, 14/12 of £550 = £612.

Estimated cost of similar in second-hand condition to first car = $\frac{£642 \times 475}{x}$.

Allowance now due is therefore $\frac{£612 \times 475}{x}$ less £230.

"M. McM." has received "another form, Schedule E 1922-23, with a slip," implying that he will now be assessable on the amount of income for the current or preceding year.

* * * Apparently the slip refers to the change effected by Section 15 of the Finance Act, 1922, transferring the assessment of income from all employments to Schedule E. If, however, as we understand, our correspondent's income is derived from his own medical practice, it is still assessable on the three years' average of that income, as the above section has no application to the assessment.

"W. H. N." writes with regard to the assessment of board and lodging.

* * * The slip enclosed seems to have no reference to this point—see reply to "M. McM." above. Further, the Finance Act, 1922, appears to leave the law untouched as regards the chargeability of board and lodging—namely, that if the receipt is in kind so that it is not capable of conversion into money it is not taxable (Tennant v. Smith), but if the salary is in terms of money subject to a deduction for estimated cost of board and lodging then the whole salary is taxable as the amount retained by the "employer" is not paid for professional expenses.

RELIEF OF PAIN IN ACROMEGALY.

Dr. W. GOWER (Hastings) writes: I have under my care a patient with acromegaly who is having the usual recurrent headaches but of most appalling severity; morphine gives some relief, but the condition of the patient is otherwise so good that she will long outlive the usefulness of morphine. I should be very glad for any suggestions as to medical treatment of this condition.

LETTERS, NOTES, ETC.

AN OLD WIVES' FABLE.

Dr. J. B. HELLIER (Leeds) writes: I have lately been re-reading Mrs. Gaskell's *Cranford*, with its delightful presentation of early Victorian ways and notions. In Chapter V there is a curious obstetrical point. A mother writes to her daughter, who has just been confined, begging her when she left her room, whatever she did, "to go up stairs before going down." This curious and apparently irrational advice to make the greater exertion before the less is perplexing. Cranford is said to be Kuntstford in Cheshire. I wonder whether any practitioner in that district, or in any other part of the country, has met with this superstition and can shed any light upon its origin and significance.

ARTIFICIAL EYES FOR OPHTHALMOSCOPIC STUDY.

Dr. CHARLES J. HILL AITKEN, M.D. (Kilnhurst, nr. Rotherham), writes: I learnt the way to handle the ophthalmoscope and the retinoscope by using the artificial eye. When expert in handling the instruments I advanced to the human subject. From personal experience I can strongly recommend the artificial eye as the first step in ophthalmoscopy.

FOREIGN BODIES IN AUDITORY MEATUS.

Dr. ARTHUR T. JONES (Mountain Ash) writes: May I also add a case that came to my notice? A woman over forty years of age came to my surgery complaining of deafness. On examining the ear there was something dark to be seen which I concluded was wax. I syringed the ear and out came a piece of slate pencil about half an inch long, which I showed the woman. She then exclaimed, "It must have been there thirty years. I remember it when I was a girl at school." It had apparently caused her comparatively little trouble.

SPANISH POPES.

Dr. PERCY C. GARRETT, Cheltenham, writes: In the JOURNAL of June 24th, p. 1005, Calistus III is referred to as "the only Spanish Pope." Surely his nephew Rodrigo Lancet, afterwards notorious as Rodrigo Borgia, Alexander VI, was equally Spanish, both in birth and sentiment. I think I am correct in saying that Spanish was the language of his family correspondence and family life at the Vatican, and that his policy was mainly that of co-operation with Spain, until his ambition for his beloved Caesar, for whom he obtained a French dukedom and a French wife, led him to incline to the side of France.

MEDICAL GOLFING SOCIETIES.

THE Medical Golfing Society were entertained on Wednesday, July 12th, by Sidecup Golf Club, and played a match against that club. The match was one of eleven a side, and resulted in a win for Sidecup by 6 to 3, with two matches halved. In the first five matches T. P. Kolesar and H. Gardiner-Hill halved with J. Chilton and C. H. Pillman respectively. R. Bristow beat C. H. Myrtle by 4 and 3, while L. Bionley lost to A. M. Johnstone by 2 and 1, and Sir R. Cruise defeated A. S. Myrtle by 2 up. In each match the representative of the Medical Golfing Society is mentioned first. The thanks of the Society are due to Sidecup Golf Club for this kindness and hospitality with which they were entertained.

The tie for the Lancet and Henry Morris challenge cups was played off on June 8th, and was won by Mr. T. P. Kolesar, Mr. H. D. Gillies being one down.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 32, 33, and 34 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 40.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.
All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-
vante letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

69. Classification and Therapeutics of Diabetes Mellitus.

LABBÉ of Paris (*Rev. Méd. de la Suisse Romande*, May, 1922) reviews the present state of knowledge of this disease, and, while criticizing the older classifications, can find none that is entirely satisfactory. Diabetes is a pathological condition in which the system has wholly or partially lost the power to utilize carbohydrates obtained from food, resulting from alimentary metabolism, or from tissue destruction. Its chief characteristic is a permanent difficulty of "glyco-regulation." He adopts H. Labbé's classification: I. Diabetes without "nitrogen denutrition," in which there is only difficulty of carbohydrate metabolism. II. Diabetes with "nitrogen denutrition," where the failure of carbohydrate metabolism is associated with failure of protein and hydrocarbon metabolism, representing the gravest factor. Class I corresponds to those formerly described as "fat" or "arthritic" diabetics. Their glycosuria is usually moderate, but may be increased by overfeeding. The amount of sugar alone does not indicate the severity, and varies with the hydrocarbon ingestion, but the daily loss of sugar in the urine is always less than the quantity of carbohydrates taken—that is, the patient maintains some capacity for utilizing them. That degree of tolerance indicates roughly the gravity of the case. A more exact estimate of ability to oxidize carbohydrates is to reduce them till the glycosuria has disappeared, and then to increase them until sugar reappears. This limit of tolerance may be maintained for years, but may be varied—for example, by the occurrence of an acute infection. Nitrogenous metabolism is unchanged. II. Diabetes with "nitrogen denutrition," formerly termed "wasting" or "pancreatic diabetes"—a bad term, for the pancreas is not more often diseased in these cases than in Class I. The quantity of sugar excreted is greater than that of carbohydrates ingested and the excess is provided by protein and hydrocarbon metabolism. Glycosuria never disappears when carbohydrates are withheld. The failure of protein metabolism is shown in two ways. (a) There is a constant intermittent loss of nitrogen, averaging 1 to 3 grains daily. The nitrogenous equilibrium is destroyed, and the patient's fate is inevitable. (b) Nitrogen metabolism is incomplete, by-products—ammonia bases, amino-acids, creatin, etc.—appear. Blood analysis reveals the breakdown of nitrogen metabolism. Acidosis is always present and is progressive. This form of diabetes often attacks thin patients, and is never, apparently, due to overfeeding. It is occasionally hereditary and always fatal, though sometimes arrested for long periods. Between these two classes are those cases which show moderate and transient "nitrogen denutrition" and acidosis. Prognosis should be founded not only on the physio-pathological classification but on a knowledge of the evolution of the disease. In regard to therapeutics, there is no specific treatment; arsenic, pancreatic extracts, alkalis, and natural mineral waters act favourably in associated troubles, in hepatic congestion or cirrhosis, in pancreatic insufficiency, and on the general health or when acidosis is imminent. Regulation of diet is the only efficient treatment, but each form of the disease has its special indications. In Class I the diet should be mixed, with reduction of carbohydrates below the tolerance limit, and meat should be reduced in quantity, lest serious acidosis supervene. To produce a rapid result, the patient may be ordered a green vegetable diet; this has yielded excellent results. In the grave forms of Class I, when glycosuria persists in spite of this diet, the patient should be ordered to fast for two to four days. The author has published cases which show this treatment to be both harmless and very beneficial. In Class II a mixed diet, with reduction of carbohydrates in cases with little or no acidosis, helps to maintain nitrogenous equilibrium and to reduce glycosuria. Meats should be reduced to a minimum (*vide supra*). The "milk cure" and "potato cure" have been useful in transient acidosis, but usually increase glycosuria. Von Noorden's "oatmeal cure" is sometimes very useful when coma threatens. Leguminous vegetables offer the same advantages; on account of their large protein content they check nitrogen waste, their protein is better borne than that of meat when acidosis is imminent; 1,200 to 1,500 grams per diem of green vegetables or salads neutralizes acids and relieves hunger. Vegetables should be cooked in milk and only slightly seasoned. Butter, oil, or fat bacon may be added, and the diet may be enriched with eggs, cheese, milk, and gluten bread. Occasional fasting is often beneficial, but

if prolonged or too frequently repeated it augments tissue waste and hastens the end. In the milder cases treatment relieves symptoms, but only masks the defect in metabolism; the patient should be warned that only by strict adherence to the diet suitable to his carbohydrate tolerance can improvement be maintained. In the severer forms unhelped-for results often follow (even in children) the green vegetable and fasting treatments. The results of the "Allen treatment" have been somewhat exaggerated, but a groundless fear of acidosis should not prevent its trial in suitable cases. "While we can ameliorate the condition and retard the evolution of the gravest symptoms by physiologically sound dietetic treatment, we cannot pretend to cure diabetes."

70.

Renal Retinitis.

MOORE (*British Journ. of Ophthalmol.*, May, 1922) records an unusual case of renal retinitis in a man, aged 45, who, without any history of previous illness, complained of failing sight, the retinal changes being so severe as to produce detachment of the retina in both eyes. The retinitis and retinal detachments slowly disappeared until, at the end of nineteen months, his blood pressure was reduced and the albumin had disappeared, the only ocular change, beyond signs of secondary atrophy and attenuated vessels, being a very little exudate. During the greater part of the next five and a half years he was working overtime in a small arms factory, at the end of which time he returned under observation with blood pressure 265 mm., a heavy cloud of albumin, and the fundi but little altered since he was last seen. Shortly afterwards he was admitted to hospital and died in uraemia. The post-mortem examination showed chronic nephritis, arterio-sclerosis, untinged liver, and oedema and infarction of the lungs. Microscopic examination of the eyes showed no retinal detachment, but a slight exudate in Henle's layer in the left eye, with a peculiar localized pigment proliferation in the retina. The case is of interest on account of the length of time the patient lived after developing renal retinitis, the disappearance of the detachments, and the subsidence of the retinitis, it being comparatively rare to be able to trace its gradual disappearance to a point at which it may be said to have completely subsided. Since very few patients die in uraemia without presenting some fundus changes it would appear that this case would not have died without developing retinitis had not the eyes been protected against its recurrence as a consequence of the atrophy following the previous disease.

71.

Endo-uterine Transmission of Scarlet Fever.

COZZOLINO (*La Pediatra*, June 1st, 1922) reports the following case as a probable example of intrauterine infection of scarlet fever. The mother died in childbirth on the fifth day of scarlet fever, leaving two children, one aged 21 months and the other just born. The children were taken away, and six days later the older child developed a malignant type of scarlet fever and died in two days. It was then found that the newborn child, aged 20 days, was suffering from acute glomerular nephritis of a scarlatinal type (albumin, blood, hyaline granular casts in the urine), and a mucopurulent discharge was seen coming from both ears. No desquamation had been noted, and no rash except a slight erythema, which was probably nothing more than the erythema often seen in young babies. In due course this second child recovered. The type of nephritis and the time at which it appeared, coupled with the absence of any other known cause, make it highly probable that this was a scarlatinal nephritis secondary to an intrauterine attack of scarlet fever.

72.

Multiple Neuritis During and After the War.

KNAPP (*Deut. med. Woch.*, May 19th and 26th, 1922) has found that the incidence of multiple neuritis has increased enormously during and after the war, the number of abortive and rudimentary forms in particular being very great. The chief cause of this increase is probably due to altered and inadequate food, notably want of fats. Alcohol plays a comparatively subsidiary part, whereas nicotine is more harmful than heretofore owing to increased consumption of tobacco and to deterioration of its quality. The success of interdicting the use of tobacco was in many cases so complete that there could be no doubt as to the cause of the multiple neuritis. In several cases it was associated with vaccination against typhoid fever and hydrophobia, intercostal neuritis being observed on the same side of the chest as that on which the vaccine was injected. In spite of the severe pain in the legs they usually ran a favourable course. 151 A

important cause of the increased frequency of multiple neuritis during the war was CO poisoning, against which the German gas masks were ineffective. The author himself was dragged out unconscious from his quarters in the Siegfried line, and the headache, giddiness, and nausea which he experienced at first having passed off completely, he thought he had escaped scot free. But fifty hours later he developed multiple neuritis. Probably many cases of relapsing multiple neuritis at the present time have their origin in gas poisoning. The author also discusses the relation of multiple neuritis to acute articular rheumatism, suggesting that the two may be the different expressions of one and the same infective agent. At all events the association of these two diseases is too frequent to be accidental.

73. The Cardiac and Aortic Complications of Malaria.

TREMOLIERES and CAUSSADE (*Rev. de méd.*, March, 1922) made observations on 1,000 cases of malaria, among which they found 42 with cardiac affections. All were soldiers, aged from 23 to 40, who had been in Macedonia for a period ranging from a few months to two years, and had been repatriated for malaria. The cases were classified in two groups, according as malaria alone (34 cases), or another cause as well (8 cases), was responsible for the cardiac condition. Each group consisted of three categories, the first comprising functional disturbances, such as precordial pain, palpitation, breathlessness, and tachycardia; the second, aortic lesions, with or without endocarditis; and the third, myocardial lesions. As a general rule, the functional disturbances and the aortic and myocardial lesions all appeared at an early stage of malaria, but did not cause the patient any distress until several months or even a year later. In every case but one the general condition remained satisfactory. Malaria was found to have a predilection for the arterial system, as was shown by the frequency of renal sclerosis, generalized arterio-sclerosis, and Raynaud's disease among these patients. The hypothesis of cardiac lesions of endocrine origin is also plausible, suprarenal insufficiency having been demonstrated in a number of cases during the war (Palssean and Lemaire). The prognosis of cardiac affections of malarial origin depends partly upon the nature of the cardiac lesion, but the following unfavourable factors must also be considered—namely, organic enfeeblement due to malaria, and the possibility of repeated attacks, with their prejudicial effect upon the cardio-vascular system. Treatment entirely depends on the heart condition, on which quinine has no effect.

SURGERY.

74. Dilatation of the Oesophagus.

DIFFUSE dilatation of the oesophagus may be thoracic, or thoracic and cervical. Often only found after death, it may be recognized during life by x rays and the oesophagoscope. SARGNON (*Rev. de lar., d'otol. et de rhinol.*, May 31st, 1922, p. 395), in discussing this condition, says it may attain large dimensions, and may be found in children and adults. It may first give rise to symptoms in adolescence, with slowly increasing dysphagia; it rarely has a sudden onset, except in spasmodic conditions or when of inflammatory origin. The progress of the case shows four signs which make diagnosis easy: regurgitation during or after a meal, containing mucus and recent or old particles of food; radiographic examination to exclude the presence of an aneurysm, whilst the opaque meal shows the dilatation; the passage of bougies differentiates the spasmodic and inflammatory strictures; whilst the oesophagoscope confirms the x-ray findings, and should be carried out under cocaine anaesthesia. The condition may terminate with progressive wasting and complete attacks of dysphagia, rarely haemorrhage or compression of neighbouring organs. Three types of mega-oesophagus are described: (1) the congenital type due to a congenital valve; (2) due to spasm and with large pocket formation and easy passage of bougies; (3) the inflammatory type may be rapid in onset and passage of a bougie may be difficult or impossible without the assistance of the oesophagoscope. The treatment for these conditions is medical or surgical. Medical consists in tonics, hydrotherapy, careful attention to diet, avoidance of spices, and slow mastication. Surgically, high-frequency currents have been applied locally; in non-inflammatory conditions the passage of bougies. Where there is a stricture the bougie is guided by the oesophagoscope. Gastrostomy may be performed and retrograde dilatation. As a last resort and in bad cases gastrostomy should always be done; this gives the oesophagus rest, supplies the patient with nourishment, and later allows treatment of the stricture, or whatever condition is found, to be carried out.

75. Gastric Tumour of Nervous Origin.

MATHIEU (*Bull. et Mém. de la Soc. de Chir. de Paris*, May 23rd, 1922) reports an interesting case of a pediculated tumour removed from the pyloric region of a patient aged 50 years. Pathological examination of the specimen showed that it was a tumour of nervous origin, analogous to the growths sometimes found in the viscera in Recklinghausen's disease. The patient had not exhibited any other symptoms of this affection. It is generally recognized that a tumour of nervous origin may arise from the sheath of Schwann, and the writer suggests that in all probability this was the nature of his case. This patient did not exhibit any cutaneous nodules, such as one usually finds in Recklinghausen's disease. These neuro-fibromata arising in connexion with the viscera appear to be rare. Lecène reported a case of fibro-sarcoma of the small intestine in a patient who showed multiple pigmented areas and small nodules scattered over the whole body. He resected the intestine and attached tumour and the patient recovered. Recklinghausen himself has described, under the disease which bears his name, tumours of this nature: in one case he records two sarcomatous stalked tumours arising, one from the stomach, the other from the jejunum.

76. Haematoma of the Rectus Abdominis Muscle.

PERMAN (*Acta Chirurgica Scandinavica*, April 29th, 1922) has come to the conclusion that haematoma in the sheath of the rectus abdominis muscle is of common occurrence, and he records eleven cases of his own as well as reviewing the accounts of nine cases published by other writers. According to some authorities the diagnosis is easy, but, as the twenty cases under review show, this opinion is incorrect. Only in six of the twenty was the right diagnosis made or suspected before operation. In no fewer than six cases torsion of an ovarian cyst was suspected, and in three of these cases the hypothetical ovarian cyst was distinctly palpated through the vagina. In these cases the large haematoma was in the lower part of the sheath of the rectus, where it bulged into the abdominal cavity. Ruptured intruterine pregnancy, intestinal obstruction, appendicitis (several cases), incarcerated hernia of the abdominal wall, tumours of the abdominal wall, and various other conditions were diagnosed by mistake. A haematoma in this position may disappear without complications under conservative treatment, but in as many as seventeen of the twenty cases the haematoma was evacuated by operation. In addition to trauma, which plays the most important part, typhoid fever and influenza are apt to give rise to this condition and to lead to suppuration. In these circumstances opening and drainage are imperative, whereas a small traumatic haematoma may well be left alone.

77. Surgical Complications of Acute Middle-ear Suppuration.

MYGIND (*Hospitalstidende*, March 15th, 1922) has performed 1,000 operations in the period 1905-20 on the mastoids of 830 patients, some of whom were operated on twice on the same side, and others on both sides. He found that influenza played a most important part in the etiology, and that the germs responsible in an overwhelming majority of cases were streptococci. The mortality among the streptococcal cases was particularly high. Only in 1.4 per cent. of the children operated on were tubercle bacilli found in the pus, but the author considers that this figure greatly under-estimates the frequency with which the tubercle bacillus is responsible for the disease. With regard to treatment, he does not recommend opening up the mastoid when, in the first stage of acute suppurative middle-ear disease, simple periostitis of the mastoid develops, even when this is associated with considerable swelling. But periosteal swelling at a later stage indicates more deep-seated disease and calls for more radical treatment. In about a third of all his cases the periostitis led to a subperiosteal abscess, which was three times more frequent among children than among adults. Thrombophlebitis occurred in 5.2 per cent. of all his cases, and was almost twice as frequent among adults as among children. Recovery from this complication occurred in 60 per cent.; among children 70 per cent. recovered. All the seven patients suffering from thrombophlebitis with metastatic complications in the joints, tendon sheaths, and bursa recovered. But thrombophlebitis with pulmonary metastases proved almost invariably fatal. In 6 per cent. of the children and 9.1 per cent. of the adults there were signs of meningitis before the operation. In 46 per cent. of the children and only 10.5 per cent. of the adults the meningitis ended in recovery. With regard to the high mortality among children suffering from middle-ear disease, the author points out that most were already weakly or tuberculous children, and that among children who were healthy apart from the middle-ear disease the mortality was very low indeed.

78. Selenium in the Treatment of Malignant Disease.

GILLET and WAKELEY (*British Journal of Surgery*, April, 1922) report the result of the employment of selenium in the treatment of malignant disease in over one hundred cases. With regard to dosage, they find that a large dose (5 c.cm.) if continued week by week spells disaster, and that a smaller dose should be given immediately after the maximum reaction has been obtained. A lower average dose was the only method by which a focal reaction of such urgency as to necessitate cessation of treatment could be avoided. A leucocytosis was present after the earlier injections, but not after the later ones; this explains the apparent improvement often referred to by the patient. Further, after the first few injections the toxæmia is diminished, with a concurrent improvement in the patient's general health. Selenium combined with x rays or radium was not found to be of benefit. Pain and insomnia are aggravated in most cases. On these grounds, or because of the severity of the local reaction, the injections have to be suspended. The weight of the patient follows the same course as in every malignant lesion. The authors have observed no gain in weight during the treatment. The conclusions arrived at are that temporary improvement is the most that can be expected. To obtain temporary improvement small doses are essential, the number of injections being limited to eight or ten.

79. The Complement Fixation Test for Hydatid Disease.

FAIRLEY (*Med. Journ. of Australia*, April 1st, 1922) describes his technique for the complement fixation test for hydatid disease and discusses its clinical value from observations of 153 cases. The reaction is specific, depending upon the presence of specific antibody in the blood or body fluids of patients who have been absorbing hydatid antigen derived from the cysts of *Taenia echinococcus*. The most effective antigen consists either of hydatid fluid containing scolices collected under sterile conditions from the liver or lung cysts of sheep, or of a saline, or alcoholic, extract of well-washed scolices. The serological test described was applied in 1,070 cases, in 917 of which there was no evidence of echinococcosis, and in none of these was a misleading positive or pseudo-positive reaction obtained, thus pointing to the absolute specificity of the test. The value of the reaction in preoperative diagnosis in 83 cases of hydatid disease is shown by the high incidence (84.3 per cent.) of positive serological diagnosis, 70 out of the 83 cases being rightly diagnosed as hydatid, while clinically only 31 were definitely diagnosed, the remaining 52 being doubtful or not suspected. The persistence of the reaction twelve months after operation is diagnostic of the presence of another cyst, and, given reasonable grounds for suspecting its location, laparotomy is indicated. Absence and non-reappearance of the reaction within a few months of operation would afford ground for an optimistic prognosis as regards the chance of recurrence.

OBSTETRICS AND GYNAECOLOGY.**80. Fibromyoma of the Broad Ligament.**

ACCORDING to TURCO (*Annali di Ostetricia e Ginecologia*, May, 1922), fibromyoma growing primarily in the broad ligament is not uncommon; Strohecker in 1903 was able to collect 73 cases from the literature. Women aged from 30 to 50 are most frequently affected, and the tumour appears, as a rule, to grow more slowly than is the case with uterine myomata, although both have the same histological characters. Pedunculated fibromyomata, usually attached to the upper portion of the ligament, are less common than sessile tumours occupying its middle portion; the larger growths are often lobulated. Probably some fibromyomatous tumours of the broad ligament have in the first instance grown in connexion with the uterus and have acquired a secondary vascular supply independent of that organ; a primary fibromyoma of the broad ligament is situated external to the uterine artery, and may arise in the muscular fibres which are normally contained within the connective tissue of the ligament, or possibly in embryonic remnants of Müllerian origin. The tumours are not rarely oedematous, but cystic, calcareous, fatty, or malignant changes are uncommon. The most characteristic clinical picture is that of presence of pelvic tumour with compression signs but absence of morbid menstrual changes; pre-operative diagnosis, however, is difficult. Turco records three cases treated by laparotomy and enucleation; hysterectomy also is necessary in many cases. For the rare case in which an intraligamentary tumour is diagnosed before operation Tricomi has proposed an extraperitoneal removal, approach being made as for ligature of the common iliac artery.

81. Tubal Pregnancy Recurring on the same Side.

SIGWART (*Zentralbl. f. Gynäk.*, May 6th, 1922) states that about 5 per cent. of cases of tubal pregnancy have been preceded by pregnancy in one or other tube, treated at antecedent operation. The recurrence of ectopic gestation on the same side is somewhat rare, fewer than twenty instances having been recorded in the literature. The writer records the case of a girl, aged 23, in whom the right tube with the exception of a minute stump of the isthmus was removed at operation for rupture of tubal gestation; four months later similar acute symptoms ensued, and at operation a developing ovum was found embedded in the tubal fragment and fading secondary attachment to a loop of small intestine. Recurrence of extrauterine gestation in the ampullary portion of a tube partially removed at operation has been described by Bracht, in a case, moreover, in which the ostium abdominale was certainly occluded. Sigwart records also an instance of recurrence of tubal pregnancy, necessitating a second laparotomy, in a patient in whom the whole of the isthmic portion had been left behind. Ectopic gestation in a tubal stump which had not been excised at operation for adnexal disease has been recorded in several cases. The practical conclusion to be drawn is that whenever possible careful suture of the tubal stump should be practised, either by removal of a wedge-shaped piece of the isthmic region of the uterus as recommended by Stoeckel, or by careful coaptation of the peritoneal remnants. The recurrences of ectopic gestation have taken place for the most part in cases in which the serious condition of the patient at the time of the first operation had rendered these procedures impossible.

82. Conservative Operation for Ectopic Gestation.

DOSSENA (*Annali di Ostetricia e Ginecologia*, May, 1922) pleads for a more frequent conservation of the Fallopian tube at operation for ectopic gestation, and records eleven cases in which Maugliagalli at the Milan Scuola di Ostetricia refrained from salpingectomy; the recoveries were uneventful, and four pregnancies have so far followed. Salpingectomy is certainly indicated where tubal rupture, with tear of the wall, has occurred; it is, however, unnecessary in certain cases of tubal abortion. Provided that the integrity of the tubal wall is complete, that there are no long-standing adhesions with neighbouring organs, that the permeability of the lumen can be demonstrated by passage of a sound, and that the ovary of the same side appears to be perfectly healthy, it is correct, in young patients, to refrain from excising the gravid tube; if that tube is found empty at operation peritoneal toilet and closure of the abdomen are all that is required, but a partial tubal abortion is first to be completed by gentle digital compression. According to the author, in cases of tubal abortion (although not of rupture) all danger of bleeding ceases when the gestation sac has been emptied. Although it has been argued that to leave the tube *in situ* is to subject the patient to the danger of recurrence of tubal gestation, it is by no means certain that the cause of this condition lies in morbid tubal changes, either of one or the other side. A third objection to conservative treatment is that there is danger of development of malignant disease from decidua remnants left behind; only three such cases appear, however, to have been recorded.

83. Influence of Diet on the Incidence of Eclampsia and Albuminuria.

RUIZ-CONTRERAS (*Zentralbl. f. Gynäk.*, May 13th, 1922), working in a Barcelona ante-natal clinic, found albuminuria to be present in 2 per cent. only of pregnant patients and fewer than one case of eclampsia in 400; at the same time both conditions were considerably more frequent in private practice. The difference he attributes to a difference in diet among the poorer and richer sections of the community. The finding is similar to that of diminished incidence of eclampsia and albuminuria in Germany during the great war, but whereas German reports usually explained the difference as being due to scarcity of fat during the war, the writer believes that the only significant difference in the dietary of his two classes of patients concerned protein foodstuffs. Coincidentally with the increase of wages which followed the armistice the figures of the Barcelona clinic showed an increase both of albuminuria (6 per cent.) and of eclampsia (3 per 1,000).

84. Metastatic Ovarian Cancer.

VAN DOUGEN (*Nederl. Tijdschr. v. Geneesk.*, April 22nd, 1922) remarks that it was formerly believed that secondary cancer of the ovary was exceptional, but that now this opinion is no longer held, some authorities, such as Bland-Sutton, believing that ovarian cancer is almost always secondary. In more than half the cases it is bilateral and may rapidly attain a considerable size, so as to give the impression of being

a primary growth, as in a case observed by Van Dongen in a woman, aged 56, of colloid carcinoma of both ovaries secondary to carcinoma of the appendix. Van Dongen also reports a case of unilateral carcinoma of the ovary secondary to cancer of the stomach in a woman aged 38, associated with pregnancy. Premature delivery took place in the sixth month, followed by death three weeks later. The association of pregnancy with ovarian cancer is very rare, owing to the fact that the favourite time for the development of a new growth in general, and of cancer in particular, is after the menopause.

85. Labour under Hypnosis.

KIRSTEIN (*Zentralbl. f. Gynäk.*, May 27th, 1922) quotes the results reported from the Heidelberg clinic of conducting labour in patients hypnotized during the early stages, and previously prepared by suggestions made during three or four preliminary attendances at the clinic. Von Oettingen had two failures among 16 labours; Schultz-Rhönhof, 8 among 77. The writer endeavoured to modify the technique so as to make it less exacting for the physician; in the preparatory sittings the suggestion was impressed that the patient, after being hypnotized by the physician, would sleep through a painless labour and would only awake on receiving the command to do so from the doctor at a time when birth had been accomplished. The nurse was instructed to reinforce these suggestions, should the patient prove restless, by application of an empty ether mask and by saying, "Go on sleeping quietly until the doctor comes and wakes you." In 14 out of 22 cases this method led to satisfactory results, the conduct of labour being left to the nurse, and the patient being awakened by the doctor at his routine visit, which took place in several instances on the day following the birth. The writer speaks favourably of combination of hypnosis with narcosis, as recommended by Friedländer; the nurse is authorized to administer 3 to 5 drops of chloroform during each pain. The case is recorded of a vaginal Caesarean section performed for valvular disease of the heart with failing compensation and bronchitis; during the operation, which lasted 110 minutes, the patient, after initial induction of hypnosis, received 70 c.cm. of ether; she replied to questions but was not restless, and no recollection of the operation was subsequently preserved.

PATHOLOGY.

86. Bacteriotherapy in Typhoid Fever.

It has long been a moot point whether prophylactic injection of typhoid vaccine has any effect in altering the course of an attack of enteric fever—should it subsequently develop—or whether it acts merely by diminishing the chances of contracting the disease. Some very interesting observations on this point are brought forward by H. E. DUFFAU (*Arch. Inst. Past. de l'Afrique du Nord*, 1922, No. 1, vol. ii, p. 53). A detachment of soldiers on a march halted at a certain place, notorious as an endemic centre for typhoid. They reached their destination the following day. Twelve days later some of them were vaccinated with 2 c.cm. T.A.B. vaccine, which some—for special reasons—were excused. In the subsequent ten days a small epidemic of typhoid fever broke out in which nine men were attacked, five of them vaccinated, four of them unvaccinated. A description, with the temperature chart appended, is furnished of each of these cases. Two points are very striking. In the case of the vaccinated soldiers not only were the symptoms of the disease very mild, but without exception the disease ran its course completely in ten days. On the other hand, with the unvaccinated men the symptoms were much more severe—one had a severe intestinal haemorrhage—and the disease ran its usual course of eighteen to twenty-four days; two of the cases, moreover, had short relapses. It must be remembered that the inoculations were made just at the end of the incubation period; this would seem to suggest that bacteriotherapy might give favourable results in enteric fever if employed at the very onset of the disease.

87. The Haemoclastic Reaction in Normal and Abnormal Pregnancy.

ACCORDING to DIDIER (*Gynecol. et Obstét.*, 1922, v, 5), the haemoclastic reaction evoked by administration to the fasting patient of proteins (milk or meat) is absent during the first five months of gestation, but present in 35 per cent. of gravid patients, irrespective of the duration of pregnancy. A reaction is present in about 60 per cent. of pregnant patients after ingestion of sugar. No parallelism is shown by the reactions with each other, or with the presence of urobilin or bile salts in the urine, or with Mallard's coefficient. In abnormal

pregnancy the author has made the following observations: Patients, primiparous or multiparous, suffering from complications of pregnancy such as did not affect the liver, showed absence of the haemoclastic reaction up to the sixth month but presence of the reaction in 42 per cent. of cases near term. In a second group of cardiopathic, syphilitic, or tuberculous patients, the haemoclastic reaction was somewhat more often positive, but had no significance as regards prognosis or severity of the complications. In a third group in which the patients suffered from albuminuria, oedema, pyelonephritis, or icterus, 10 albuminuric subjects showed a positive reaction in 8; 5 women with oedema but no albuminuria showed a positive reaction in 4; and 2 of 4 jaundiced patients reacted. The conclusions are drawn that especially during the first five months of gestation the pregnant patient in normal conditions does not generally show evidence of toxæmia of hepatic origin; and that pregnant patients manifesting simple oedema without signs of hepatic insufficiency are more generally than is commonly supposed the subjects of hepatic derangement.

88. The Mechanism of Neutralization of Acid Secreted by the Kidneys.

AN interesting explanation of the renal secretion of acid is put forward by AMBARD and SCHMID (*C. R. Soc. Biologie*, April 23th, 1922). Organic acids, such as aceto-acetic and oxybutyric, are excreted by the kidneys in the free form, while the inorganic acids, such as hydrochloric and sulphuric, can only be eliminated when combined with bases. One knows that in herbivora this neutralization is performed by sodium and potassium and in carnivora by ammonia; this difference is dependent solely upon the altered character of the diet in the two classes of animals, for it has been shown that herbivora fed on urea react to intoxication by acids by the production of ammonia, while carnivora, on the other hand, if deprived of nitrogen, have recourse to their reserve supply of alkaline bases to combat acidæmia. In explanation of this difference the following hypothesis is offered. When acid is present in the blood its passage into the kidney causes an increased hydrogen-ion concentration in the cells of this organ, which lowers the threshold of excretion for the alkaline bases. These, therefore, pass into the kidney, where they neutralize the acid which has just arrived, with the result that the latter is excreted in the form of a neutral salt. In the carnivorous animal the mere presence of an increased amount of acid in the blood brings about an increased formation of ammonia from urea, so that when the acid passes into the kidney the ammonia is there already to neutralize it. This explains why in herbivora during excretion of acid there is a fall in the alkali reserve of the blood, whereas in carnivora no such fall is observed. With organic acids, however, the case is different. Their ionization is very feeble; in consequence during the process of their excretion they do not succeed in raising the hydrogen-ion concentration of the kidney sufficiently to lower the threshold of the renal cells for the alkaline bases. No sodium or potassium therefore passes into this organ, and the acids are eliminated in the free, uncombined state. Briefly, then, acids which cause an increase in the hydrogen-ion concentration of the kidney lower the threshold for the alkaline bases; acids which are too weakly ionized to bring about such an increase are able to pass out free. Further, the greater the increase in hydrogen-ion concentration, the lower is the threshold depressed, and the more therefore is the blood depleted of its alkaline constituents.

89. Wassermann Test with Chancre Fluid.

KLAUDER and KOLMER (*Arch. of Derm. and Syph.*, May, 1922) have shown that fluid expressed from a syphilitic chancre will give a positive Wassermann reaction in the early period when the blood is still negative. The fluid was obtained by aspiration by means of a small rubber bulb attached to the end of a fine capillary pipette, and when insufficient juice could be obtained in this way the chancre was washed with saline and the diluted excretion still gave a strongly positive reaction. The presence of a trace of blood made no difference to the delicacy of the test; secondary bacterial invasion showed no disturbing effect; and local treatment with a spirochaetocidal drug, although causing the disappearance of the spirochaetes from the surface, did not inhibit the local formation of the Wassermann fixing substance. The clinical value of the test in the diagnosis of early syphilis is of definite but limited value. It cannot replace the simpler method of discovering spirochaetes by dark-ground illumination, but in those cases in which the spirochaete search has been negative, or in which the chancre has been previously treated with a spirochaetocidal drug, a Wassermann test with the chancre fluid will give a positive reaction before the test with the patient's blood gives any indication of the disease.

British Medical Association.

NINETIETH ANNUAL MEETING, GLASGOW, 1922.

President's Address

BRAIN SURGERY.

SIR WILLIAM MACEWEN, C.B.,

REGIUS PROFESSOR OF SURGERY, UNIVERSITY OF GLASGOW.

SPEAKING from the Presidential Chair my first words must be words of welcome on behalf, not only of the large body of the profession in and around Glasgow, but also of the many citizens who have joined us and who have wrought hard to express their good feeling towards our colleagues on the occasion of the Annual Meeting of the British Medical Association.

We welcome you to the city of Glasgow, the second city of the Empire, a city which within a radius of thirty miles is surrounded by half the population of Scotland.

Glasgow is governed by a civic corporation—a parliament of seventy members, composed of men of light and leading who devote their time and attention to the many problems of social life. They have blessed the city with one of the finest water supplies, obtained from a highland loch amongst the heather-clad hills, which pours its pure water into every home in the city, to rich and poor alike. One

has been carried out so successfully that the vast population is maintained in excellent sanitary conditions. Enteric fever has now no home in Glasgow. If the purity of the atmosphere is not all that it should be there are those among the corporation who are zealously searching for practical means of attaining that end. Nor can we doubt that those who by their foresight, energy, and indomitable perseverance brought the ocean to the feet of St. Mungo will in due time succeed in purifying the atmosphere. Of its further efforts much will be seen in the Health Exhibition in Kelvin Hall, given by the corporation.

Glasgow is one of the most cosmopolitan of industrial cities, and in the application of science can point with just pride to the multifarious industries which have here made a home. It is a literary as well as a great commercial centre.

THE BRITISH MEDICAL ASSOCIATION.

The British Medical Association—now holding its ninetieth annual meeting—is without exception the largest professional association of the Empire, and carries out the principle of voluntary combination for the consideration, not only of its own affairs, but also the readjustment of objects which are humane and public-spirited. It has also been the means of disseminating all that pertains to the science and art of medicine. It has about 24,000 members, drawn not only from the United Kingdom alone, but from all over the world wherever the British Empire extends.

It is no easy matter to succeed to the position filled by the long line of brilliant Presidents of the British Medical Association, amongst whom Sir Clifford Allbutt, Regius Professor of Physics, and David Drummond, Vice-Chancellor of Durham, in consecutive years filled

We have the honour to-day of receiving many distinguished colonials and representatives from overseas—men who are representative of those chivalrous peoples who abandoned their homes and callings and the many that were dear to them and flocked to the standard of the Mother Country in her struggle for the liberty of the world. We are also pleased to have associated with us to-day some of our American—used to call them cousins, we now call them brothers—brothers, who are to aid us by their fresh views on many topics of professional and social affairs. Last, but not least, we extend a very hearty welcome to the distinguished Continental savants who have honoured us by coming to share in and to enlighten our debates.

THE UNIVERSITY.

The University, in which we have been courteously permitted by the University Court to meet, is 471 years old, being founded in 1450 by Pope Nicholas V. With the exception of St. Andrews, it is the oldest university in Scotland. It has had a long roll of scholars, theologians, philosophers, scientists, and abstract thinkers among its professors and alumni, and one could profitably and fondly occupy many hours in reviewing the work they accomplished while playing their part in the history of the world. The exigencies of the hour, however, make it only possible to take a momentary glimpse, in passing, at a few of them.

Joseph Black.

Joseph Black, the greatest genius of his century, was an alumnus of Glasgow University and a pupil of Cullen. He was elected Professor in that university in the middle of the eighteenth century. In his Glasgow University lectures in 1757-58, he enunciated the doctrine of latent heat. The laws of specific heat and latent heat were discovered in Scotland. By a stroke of genius Black impeached the authority of the senses and idealized matter into force. In his investigations into the properties of heat he showed that heat ought to be removed from the jurisdiction of the senses, as heat was supersensual. Though we experienced its effects, we could only conceive of its existence. Latent heat baffles all our senses. While our feelings make us believe that heat is lost, our intellect shows that it still exists.

The process of reasoning adopted in this discovery had far-reaching effects, not only in natural philosophy, but in many other fields. An extension of it led to the recognition of the analogy of heat and light and much else. Einstein's theory of relativity is also founded on the impeaching of the evidence of the senses.

The flights of philosophy and the abstract reasoning had also a direct and practical issue. A model engine, which may still be seen in the library of the Hunterian Museum in Glasgow University, was used by Black in his lectures for the purpose of demonstrating the conversion of matter into force. The pent-up energy in a solid block of ice, by the application of heat, was converted first into liquid, then into vapour, and the vapour into energy which drove an engine—a primitive though non-productive steam engine. It was while repairing this model that James Watt, by the application of the economy of heat and the conservation of energy, invented the separate condenser that transformed the laboratory model into a practical machine capable of doing work.

The steam engine has transformed the world, adding to its material prosperity and being the greatest civilizing agency ever introduced. It would be an insult to the intelligence of Watt to deny that his work in that and other fields had been uninfluenced by the transcendent genius of Black, with whom he was for a short time associated.

Adam Smith.

Adam Smith, while Professor in Glasgow, delivered lectures in the University, containing the fundamental principles afterwards elaborated and published in his *Wealth of Nations*, a work which became the creed upon which the policy of this great nation was for many years founded, and which at that time added so much to its material prosperity.

The Brothers Hunter.

The brothers Hunter, the great anatomists and physiologists, we claim as Glasgow men. William Hunter, the elder, was an alumnus of our university. He was the better educated, the broader minded, and in some respects the greater of the two, though he has been overshadowed by his more brilliant brother. His anatomical and pathological collection is very fine, and contains some very beautiful preparations made by his own hand or under his direction. His work on the gravid uterus alone entitles him to a niche in fau, and is so true and so complete that it forms the basis of the text on that subject to the present day. William was otherwise a great collector and accumulator of treasures in art, in books, and in coins, as well as in comparative anatomy and pathology.

John Hunter was educated professionally by his brother, and through him was vicariously a student of Glasgow University. John Hunter owed his existence, as we know him, to his brother William, who instructed him in anatomy, pathology, and surgery. Not only did he do so, but, by making him collaborate with him in his penetration into the mysteries of nature, he taught him how to think and placed him on the rails of original research.

Thought is the creator and vivifier of all human affairs, and it is the progress of ideas which ultimately determines the progress of the world. Not only by his careful and persistent research, but by the holdness of his ideation and his philosophic methods, John Hunter has been placed in the same rank as Aristotle, Bichat, and Harvey. Yet during his life he stood alone—as possibly all such men must. He never had more than twenty students at his lectures, and at the beginning when a solitary student presented himself he had to ask the attendant to bring in the skeleton so that he might address them as "Gentlemen!"

At his death John Hunter's collection numbered 10,000 preparations illustrative of researches covering the whole range of the animal kingdom. That collection was given to the Royal College of Surgeons of England, and right royally those Englishmen have preserved and enhanced the donation, adding fresh increments and vivifying it by constant service. It has become one of the noblest museums of its kind.

William Hunter gave his museum and all its treasures to the University of Glasgow and left money to erect a suitable building for it.

The two brothers Hunter came from the farm of Long Calderwood, near East Kilbride, a few miles from Glasgow. On making a pilgrimage to the vicinity I called one day at a small cottage on the farm on the door lintel of which were the initials J. H. and a date, and asked the inmates whether they had knowledge of the Hunters who used to live at Long Calderwood, two of whom were great men. These folk had never heard of them! One of the inmates, a lady ninety years old asked—"What has they been doin' that ye are speerin' for them?" *Sic transit gloria mundi!*

Lister.

Lister introduced and perfected the antiseptic treatment of wounds while he occupied the Regius Professorship of Surgery in the University of Glasgow, founding his theory on the researches of Pasteur on fermentation, believing that inflammation might be due to a somewhat similar process. How antiseptics revolutionized practice all over the world does not require to be repeated here.

After spending nine of the most active years of his life and those fullest of scientific fruition, Lister passed quietly away from Glasgow, without public recognition of his services, the general body of citizens being unaware that a great scientific achievement had been wrought in their midst. It was long afterwards, when all the world wondered, that Glasgow became alive to what it had possessed—and lost!

Kelvin.

The achievements of Kelvin the great physicist are too vivid and fresh to require reminder at this time.

BROADER VIEWS OF LIFE.

"My late colleague, Sir William Gairdner, who was President of the British Medical Association in 1888, considered, in one of his erudite addresses, the Physician as a Naturalist; to-day I have to invite attention to the extension of our studies in the same direction.

Do we concentrate our studies too much on human phenomena to the exclusion of life as a whole?

Our so-called divisions of nature are purely arbitrary conveniences, having no existence except in our own minds. In

the material world there is neither break nor pause. In sense all matter is living and the term "death"—though correct as applied to individual existence—is a mere expression significant of transference into fresh forms of life.

We are but a bit of nature, and everything pertaining thereto must have a bearing on humanity. The history of the rocks, which are force in static form, affords much interesting material for the study of evolution. Aided by the disintegrating effects of myriad germs, the rocks crumble when in contact with the atmosphere, and the impalpable dust produced therefrom is converted by the action of other forms of micro-organisms into pabulum suited for plant life. The rootlets of the plants display their selective faculty on the material thus prepared. The matter of which rocks are composed, when dissolved and held in solution, is used for various purposes in the animal economy. The coral insect abstracts from the ocean calcareous matter which it deposits round itself and which collectively forms the solid structure producing the submarine basis of many islands in the warmer seas.

In higher forms of life specialized cells, the osteoblasts exercise their selective influence in abstracting from the blood stream the lime salts, which they deposit in an area in their immediate vicinity over which they have control, and in doing so arrange themselves in ordered sequence, carrying out the architectural design of bone construction according to hereditary law.

Comparative anatomy and physiology, much as they have been studied, still present many fields which have not been traversed, and from which a discerning eye may reap an abundant harvest—rich in itself, but also fraught with interest and of service in the elucidation of problems in the life of man.

Nor is it necessary to go far afield to begin such study. The lion, the elephant, and the duck-billed platypus are of great interest in themselves; but who knows about the fauna and flora of the dermal coverings and hirsute appendages of the ubiquitous mouse, which perseveringly installs itself in and near the haunts of man, and even penetrates the family circle?

What man thinks of the mouse may be summed up in the form of means of destruction—traps, gins, cats! What the mouse thinks of man would not flatter his vanity. The mouse regards man as an impotent animal who issues threats of destruction, and makes the most clumsy, short-lived attempts to carry them out; as a pusillanimous antagonist, a creature who for centuries has waged war on mice—with no effect! They are still as numerous, as bold, as intelligent, as agile, as beautiful, and as destructive as ever!

The "wee sleekit cowrin' tim'rous beastie" to this day pursues the even tenor of his way. No other animal has such opportunity of carrying disease into the domestic hearth. Mice of one kind or other attend the harvesting of grain in the field, follow it to the corn-rick or barn, infest the stores, mills, or bakeries, and are ready to attack the flour when made into bread. They go over the coats of children, diseased or healthy; they run from house to house; they lick every used plate, cup, or saucer on which there is a particle of sugar or crumb of bread. The mouse is a carrier of disease—but what are its pathological records? Is it subject to contagious diseases, and if so how does it disseminate them? Is it attacked by sarcoma or cancer, allied to that which attacks man? Even for the protection of humanity, apart from the intrinsic interest of the study, the mouse and its ways are worthy of the searchlight of scientific investigation.

Microbiology is only in its infancy. There are myriads of germs surrounding us of which we know little, and study of which offers fruitful fields for scientific research. The organisms contained in food, which are transmitted to the alimentary canal, are of many varieties, some benign and useful for the digestion, and others malignant and hurtful. The flora of the colon is a great field of study, and while there are organisms present which are not conducive to health, there are others which are necessary to the completion of digestion. The colon is an excellent incubating chamber, and instead of allowing it to grow weeds we ought to endeavour to sow in it plants which would be of use in the way of promoting digestion and in producing chemical compounds of service to man and combative of the weaknesses and diseases to which he is liable. This might be improved by introducing new organisms which would grow in the colon garden and produce therein beneficent cultures giving forth their enzymes and vitamins—inhibitory to the weeds in the canal and to their products in the system. Is it too much

to hope that such gardening, were it carried out successfully, would aid in the prevention of appendicitis, possibly might influence beneficially other diseases, such as arteriosclerosis and rheumatism, and might even have an effect in inhibiting the deposition of carcinoma? A healthy colon contributes to longevity and a happy state of mind.

Our habits of thought are so interwoven that speculative or scientific inquiry introduced into one field influences and affects other fields of cognate thought. It was research into fermentation of the juice of the grape, instigated for utilitarian purposes by the wine growers of France, that led to the introduction of the antiseptic system of the treatment of wounds. While conducting in a chemical laboratory an abstract research into the properties of nitrous oxide gas it was the coincidence of toothache in the person of the investigator that led Humphry Davy to the discovery of general anaesthesia, and which he advised for the prevention of pain during surgical operations. Though this discovery was published broadcast in the works of Sir Humphry Davy, so irreciprocal were the people of the period, especially the members of the medical profession, that for forty years that great discovery remained dormant—neglected and unused. Think of the inhabitants of the world, suffering for forty years pain and anguish that could have been prevented had the discovery been utilized!

The latter is but an illustration of many discoveries made by our own people which, after announcement, have fallen on deaf ears and have not been used until other nations have heard of them and have discerned their potentialities and turned them to practical account. Is this one of our national defects or diseases? Does it arise from want of scientific training or habits of thought among the people? Whatever it is, like our diseases, it is very costly. The nation not only loses prestige, but in one noted instance—the neglect of the utilization of the discovery of the basic salts—the nation has lost many millions a year; had we utilized it and all that followed therefrom in extended chemical research, we would have been better prepared for the great war and it would have aided greatly our economic position to-day.

Syphilis and Tubercle.

Syphilis and tubercle are both germ diseases which are still prevalent and sap the strength of the people. Is everything being done that ought to be done to stop their ravages?

Now that the Government, and the laity, have been educated by the medical profession to the fact that syphilis is a preventable germ disease, and can be stamped out by means made known to them, if this generation does not stop the disease it commits a crime against posterity.

With tubercle the problem is much more complicated, as it is a disease common to man and certain of the lower animals, and great efforts are being made by the sanitarians to combat the conditions leading to its production.

BRAIN SURGERY.

The Evolution of the Knowledge of Brain Function.

In my student days physiologists taught us that the brain acted as a whole, without recognition of localized areas within it endowed with specialized function.

In 1861 Broca demonstrated at the Anthropological Society in Paris the brain of a man who had for forty-one years lost the faculty of speech. The specimen showed softening of the third frontal convolution on the left side. Broca deduced from that and other observations that the base of the third frontal convolution on the left side was the seat of the faculty of articulate language, and further advanced the suggestion that there were probably other areas in the brain connected with localized function. Broca's discovery was iconoclastic; it shook the notion entertained regarding the unity of brain function to its foundation. Clinicians such as Charcot and Pitres were generally aware that lesions of one side of the brain were often associated with paralysis of the opposite side of the body; and Hughlings Jackson suggested that unilateral convulsions indicated in the same way disease of the opposite side of the brain. In 1869 Hughlings Jackson stated that, in his opinion, there were many limited areas in the brain connected with distinctive functions, founding his opinion on clinical experience and direct observation of pathological facts. He also foreshadowed the existence of higher psychic centres.

The views of Broca and Hughlings Jackson were subjected to much controversy and doubt. A new method of investigation was introduced by Fritsch and Hitzig in 1870, who applied the faradic current to the brains of dogs, and found

that in response to such stimulation of certain localized areas co-ordinated movements were evoked in distinct groups of muscles on the opposite side of the body. Ferrier published in 1873 the results of his memorable research on the brains of the higher apes, mapped out definite areas (chiefly in the central convolutions) which responded to faradic current, producing definite movement of groups of muscles on the opposite side of the body, differentiating areas for the various parts of the face and upper and lower extremities.

Whether deductions made from the localization of function in the motor cortex of the brain of the lower animals were applicable to man had yet to be proved. This I had the opportunity of doing, by direct observation of the effect of injuries, especially those of a limited character. By the application of this knowledge and the deductions drawn therefrom, cerebral neoplasms were diagnosed, and the restoration of function after their removal aided in confirming the localization.

Opportunities afforded for observation on man convinced me that both in Broca's lobe and in the ascending central convolutions there were areas in the brain with specialized functions, and by deduction that the same existed in other parts of the brain.

In the early seventies numerous occasions presented themselves for noticing the effects of interference with the brain of man, and it was early apparent that injury to the ascending convolutions induced motor disturbances of the opposite side of the body ending in paralysis, when due to pressure or destruction of brain tissue; and to spasms when due to irritation of the cerebral cortex. Especially were these convincing when cases of limited lesion were followed by monoplegias on the opposite side of the body.* These were relieved by operation, the function of the part being restored by the removal of the lesion from the brain. This was also demonstrated in hemiplegias, due in some cases to extra- and in others to sub-dural haemorrhage exercising pressure on the brain, and the speedy recoveries following their removal; whereas, in the intra-cerebral haemorrhages in the same regions the recoveries after removal were protracted and incomplete in proportion to the damage done to the brain tissue itself. Such traumas were not always accompanied by external evidence of injury, and where external evidence of injury did exist it did not always correspond to the damaged part of the brain.

When motor function was interfered with by pressure it was found safer to operate over the area of the brain whose function was implicated than to take external injury of the scalp or skull as a guide. Lesions of an idiopathic kind, when they presented themselves with disturbance of localized cerebral function, were exposed in the same way and where practicable were removed. Several of these idiopathic lesions were found to present most definite symptoms of their localization than most traumatic lesions. Thus, when an abscess of the brain presented itself with symptoms of motor aphasia, it was diagnosed to be located in or near the base of the third frontal convolution, where it was found; and when a tumour with multiple symptoms indicative of primary involvement of the anterior part of the left frontal lobe with secondary extension to the third convolution presented itself, the diagnosis, was made with sufficient approach to accuracy to enable the tumour to be located and removed by operation (1879), giving complete relief to the symptoms and curing the patient. There were several tumours in the motor cortex and one in the paracentral lobe diagnosed (in 1883) and operated on. All of them were diagnosed and the neoplasm successfully removed from the brain with the restoration of function. One case, described as a focal lesion in the motor cortex from which blood and disintegrated tissue were removed, was probably a disintegrated glioma into which haemorrhage had occurred—though at that time the appearances of disintegrated gliomas had not been sufficiently recognized.

* As a student of Glasgow Royal Infirmary I was given the means of studying lesions in the base of the third frontal convolutions producing motor aphasia. Two such cases were in the medical wards during these years, the lesion afterwards being verified by the autopsy. In 1873 a man was seen who had received a blow from a sharp pick over the parietal region of the right side of the skull which had driven in a small portion of the inner table of the skull. He suffered from spasms of the left hand and forearm followed by paresis. The depressed bone was found to have penetrated the dura and was lodged in the middle part of the ascending frontal convolution. It was removed therefrom along with external debris. The spasms ceased and the paresis disappeared in a few weeks. Three other cases of injury to the brain of a limited nature were seen in the early seventies which verified cerebral localization—one from the blow of a pointed knife, one from glass, and one from delf; all had penetrated the skull and dura, and small portions had lodged in the brain—producing localized lesions.

At this period Ferrier visited the Royal Infirmary, making inquiry into the function of the brain in man. The question was raised as to whether the information laid before us by Ferrier in his work on the brain of the chimpanzee had borne fruit in our operations on man—especially as to whether the ascending convolutions in man had been found to correspond in function to the analogous parts in the brain of the chimpanzee. To this question an affirmative answer was given, and it was suggested that a demonstration such as we could give would be welcomed by the scientific world, where confirmation of these points was eagerly awaited.

In the year 1888 I had the opportunity of addressing the British Medical Association on the subject of brain surgery, and then presented lesions from many different regions of the brain which had been diagnosed by localization of function and had been removed by operation.

In the years that followed much work was done by surgeons toward the elucidation of the functions of the brain, the pathology of the lesions and their mode of removal. Hughlings Jackson, Mott, and Gowers continued to give inspiration from the clinical side. Ferrier and Horsley and Beever did much painstaking investigation on the brains of a variety of animals, and their results were of much value. Horsley, Godlee, Ballance, and many of their London colleagues followed these by brilliant operations on man. Horsley was indefatigable in his research work, and everyone regrets that in his devotion to national duty his life was sacrificed on the burning plains of Mesopotamia. In these early days Ferrier in London was the *vis a tergo* to many of the surgeons and helped to stimulate and give them confidence.

In America there was likewise a vigorous growth of cerebral surgery, and those who took up the subject enlightened it, such as Allan Star, my old friend Keen—the youngest man in America—Harvey Cushing, and many others, all doing valuable and accurate work. D'Antona of Naples, Duranto of Rome, Lucas-Championnière of Paris, Bergman and Kranske of Berlin, were prominent at the earlier period of this evolution.

Sensory Phenomena—in the Post-Rolandic Convolutions.

From direct experiment on animals it was at first announced that both pre- and post-Rolandic convolutions were concerned in the production of movement, and were included therefore in the motor area. While accepting tentatively this conclusion founded on direct experiment, cases arose in man in which sensory impressions were the only phenomena produced by lesions in the cortex of the post-Rolandic convolutions. In other instances the lesion produced primarily sensory impressions, yet from extension forward the floor of the Rolandic fissure became involved and motor symptoms developed.

Such cases were recorded by me in 1888: in one of them a protospasm of the hallux was preceded by sensory impressions—what was described by the patient as a "curious sensation"—and pain in the great toe. The pain in the great toe was always present, but occasionally it became so severe as to make the patient cry out. The lesion was found mainly in the upper portion of the ascending parietal convolution; a smaller one of more recent origin was discovered in the upper part of the ascending frontal convolution, and this was the cause of the later motor spasm of the toe.

A somewhat similar instance appeared in another case in the same brain centres some years after. In this a sensory impression in the right foot heralded the invasion of the upper parietal convolution of the opposite side. The lesion was removed in a wedge-shaped portion of brain tissue. The patient quickly recovered under one dressing. The pain and previous discomfort in the foot entirely disappeared after the operation, but there was instead a numbness or—when the foot was left to itself—a "want of precise sensation of how to place the foot." Automatic associated movements, such as walking, were easy on a pavement, and when the patient concentrated attention on the movements of the foot they could be made according to will. After the first three months the patient walked very well, though she said there was still a trace of the defect "in the feeling" of the foot.

In several cases neoplasms and traumatism in the post-central convolutions produced sensory impressions in various parts of the body without motor phenomena. In some the sensory impressions were associated with motor phenomena—monospasms or convulsions—and others with paralysis. In the majority, however, the lesions in the motor

area involved both ascending convolutions, and the motor phenomena, being more obtrusive, were more noticed.

It was evident that a discrepancy, which required explanation, existed between the clinical data in man and those of direct experiment on the chimpanzee. Could it be due to the inability of the lower animals to express their sensations in language intelligible to man that the sensory phenomena were missed? Even were it so, it would not account for crediting the ascending parietal convolution with the function of producing motor phenomena when faradically stimulated.

From such clinical experience one was therefore prepared to accept the conclusion drawn from Sherrington's notable research on the brain of the higher apes in which, contrary to the deduction of other experimenters, he found that the ascending parietal convolution did not respond by production of movement when stimulated faradically. This was a comforting conclusion to the clinician, as it brought direct experimental research into line with the observation on man, and confirmed the latter in a way which would have taken many decades to have made *positive* by clinical observation alone. He showed that the ascending frontal and the floor of the fissure of Rolando alone responded to faradization, producing movements of the affected parts on the opposite side of the body. In clinical work the invading lesion does not always limit itself to special areas of localized function. When sensory symptoms, which do not prevent the use of the limb, appear primarily, they are apt to be overlooked or their importance minimized, and when by extension of the lesion into the pre-Rolandic area motor phenomena are presented, the sensory are apt to be overshadowed.

The cyto-morphology of the anterior central convolutions differs from that of the post-central. The Neister-Betz pyramidal giant cells exist in the anterior convolutions and not in the post-central. This may be made use of in examining specimens taken from the brain by operation, but cannot contribute to the primary diagnosis. The difference in the architectural arrangement of the cells in the two ascending convolutions would *a priori* indicate difference in function.

The sensory phenomena exhibited when other regions of the brain have been the seat of lesions have been previously recorded by me, and subsequent experience—by many others as well as myself—has abundantly borne out the conclusions there arrived at. The word deafness and psychic blindness have been particularly illustrated in one patient who had a lesion of the posterior area of the upper temporal convolutions with extension to the angular gyrus. This patient heard and saw physically, but did not comprehend what he saw and heard. "Hearing he heard not, and seeing he saw not." He asked for a drink and would persist in asking for it. Though the nurse had duly presented him with the drink and requested him to take it, yet he did not take it, but again repeated his request. When, however, his sense of touch was brought into play by placing the glass on his lips, he at once perceived and took it into his own hands and drank. When the lesion was removed he saw and heard correctly and appreciatively and tried to explain his previous difficulties.

Lesions in Silent Areas recognized by Distant Symptoms.

Though there are some areas of the brain whose functions we do not yet know sufficiently to enable us to determine when they are invaded by small neoplasms, yet when these neoplasms increase in size sufficiently to involve adjacent parts, by pressure or otherwise, the implication of these parts, in definite order, aids in indicating the position of the lesion in the silent area. Take, for instance, the invasion of the temporo-sphenoidal lobe by large neoplasm.

Localizing Symptoms of Large Abscess and Neoplasms in the Temporo-sphenoidal Lobe.

While localizing symptoms of a small abscess situated in the middle of the temporo-sphenoidal lobe above the tegmen are still insufficient to enable one to make a definite diagnosis, the symptoms occasioned by a large abscess (or tumour) in that region are quite pronounced. This symptom complex of large lesions in the temporo-sphenoidal lobe was pointed out by me in 1884 and again in my address in 1888. Since then it has borne the test of further experience. The symptoms are due to pressure extending upwards from the temporo-sphenoidal lobe to the adjacent structures and affecting them in ordered sequence. They are, first, a passivity over the face on the opposite side from the lesion, which as the lesion extends becomes a definite paresis, and may ultimately pass

into paralysis. The facial paralysis is, however, like that from all lesions of the facial centre of the cerebral cortex, not complete, as the power of emotional expression is retained to a slight degree, and the patient has the power of closing the eyelid by an effort of will, though it remains partially open during sleep. This is of importance as, in many cases where the temporal lobe is affected, facial paralysis is present on the same side as the lesion, and as it arises in such a case from damage to the nerve trunk it is complete. The power of emotional expression is not retained in the upper part of the face.

The arm on the opposite side from the lesion becomes affected with paresis after the involvement of the face, and it may become completely paralysed—though in abscess it is seldom allowed to reach that stage. The leg is not affected.

Coincidentally with the facial paresis, and sometimes preceding it, there is dilatation of the pupil on the same side as the lesion, along with a degree of ptosis when the neoplasm is large. The pupil on the same side as the lesion is affected early, but at first so slightly that the degree of dilatation may easily be missed unless specially looked for and both eyes tested for accommodation. It soon becomes dilated, however, and very sluggishly responds to light and accommodation, and latterly it becomes fixed—stable mydriasis. The ptosis is usually very slight, and may be absent. The explanation of these phenomena is simple if one looks to the contour of the cavity which contains the temporo-sphenoidal lobe, which elsewhere has been described by me as a "box without a lid"—so that the way pressure from within can be relieved is upwards, and consequently the motor cortex becomes affected, while the third nerve is caught by pressure against the posterior clinoid process.

The same symptom complex was found by me to accompany a tumour growing in the temporo-sphenoidal lobe and displacing the brain tissue upwards.* The symptoms succeeded one another very slowly but in perfect sequence.

The varieties and characteristics of cerebral tumours are now well known. We have the simple subdural meningeal fibromata which exercise pressure on the brain and which are so easily removed—of which this is a specimen [tumour shown]. It was forcibly ejected so soon as the dura was opened, the cerebral pressure within speeding the parting guest. At the other extreme we find the sarcomas of the meninges and gliomata of the brain, which are both often difficult to eradicate. It would be impossible to go into these cases in series within the limits of this address. Attention is, however, drawn to one or two cases illustrating special points.

The size of the tumour of the brain ought not alone to determine the question of removal. The smaller the tumour the greater the credit in diagnosing and removing it, as extent of invasion and the pressure effects therefrom will be the less. The larger the tumour the greater is the destruction of brain tissue and the greater will be the encroachment on the membranes and cranial walls necessary to give relief. One ought not, however, to be deterred from operating on a large tumour merely on account of its bulk, as in most cases the opening of the cranial walls will at least give relief to symptoms and often will retard or prevent blindness ensuing upon optic neuritis with choked disc. Some of the larger tumours are amenable to removal with good results, as, though large, they are of a nature which lends itself to easy removal, because the tumour has undergone degeneration. After such operation many patients have experienced relief of symptoms and restoration of function. The following are examples.

A Glio-sarcoma of Large Size occupying the Fissure of Sylvius: Removal.

As an instance of this kind, take the case of a young man of 18 years, who had pressure symptoms for over two years before coming under observation. When seen by me he had inequality of the pupils, the left being dilated and fixed, and there was a degree of ptosis of the left eyelid. The sight was markedly diminished from choked disc and nerve atrophy. He would probably have had at an earlier period partial hemianopsia, but that could not now be determined.

There was marked paralysis of the right side of the face and paresis of the right arm which had come on subsequently to that of the face. There was slight motor aphasia and also psychic blindness and a degree of psychic deafness. The general symptoms of brain pressure were marked. The symptoms pointed to a tumour of large size in the fronto-temporal region involving the central convolutions. Percussion over that area elicited a differential "hollow" note.

* Wertheim has subsequently also drawn attention to the affection of the pupil—dilatation and ptosis consequent on pressure on the trunk of the nerve on the same side.

The temporo-central region was freely exposed, showing flattened cerebral convolutions of a yellowish discoloration. There was no brain impulse to sight or touch. The cerebrum was under much pressure, and though the aperture in the membranes was large the cerebrum bulged considerably beyond the limits of the wound. On deep palpation a slight degree of semi-fluctuation was detected. An incision into the brain itself, half an inch in depth, allowed the exit of a gelatinous amorphous material which, on first opening, was for the most part ejected with considerable force. The remainder had to be removed by spoon. The walls of this large cavity were very thin and friable and broke on removal.

When the tumour was dissected off the whole length of the Sylvian fissure with its vessels lay exposed, the tissues being flattened. The bases of the central convolutions were fused and crowded together so as to be barely recognizable. The island of Reil was not visible—whether it had been destroyed in the growth or had been pulped by pressure was a question. The temporo-sphenoidal lobe was much compressed and its convolutions fused together.

The structure of the tumour, judging from the fragments secured, was that of a glio-sarcoma which had undergone extensive cystic degeneration. It had probably sprung from the upper convolutions of the temporo-sphenoidal lobe and invaded the Sylvian fissure under the island of Reil and pressed the various convolutions aside. It had exercised forward pressure so as to implicate the third frontal convolution or the fibres therefrom, pressed the third nerve against the posterior clinoid process, and probably affected the chiasma. It occupied such a large space—from the posterior part of the temporal forward to the frontal lobe and upwards into the fissure of Sylvius—that one feared the effect of removal owing to its bulk. The patient, however, after recovering from the immediate effects of the operation, rapidly became conscious, and was greatly relieved that his headache and pain had vanished. The paralysis and paresis of the affected parts lessened after the first week and gradually disappeared. At the end of six weeks he was able to walk well and use his arm freely, the paralysis of the face having also cleared away—all but a slight passivity on smiling. The sight, however, did not recover, the atrophic changes in the nerves having been too pronounced. With this exception he lived well for six years, was able to take walks in the country every day, and had commenced typewriting and braille and music. He had no recurrence of the tumour formation. Death was due to what was reported as a severe attack of influenza with pulmonary trouble.

Deep-seated Tumour situated in the Conducting-Sensory and Motor Paths of the Left Hemisphere, and involving the Lateral Ventricle.

The patient, whose powers of introspection were well developed, graphically described her sensations at the early period of her illness; the following is a summary:

She had a period of malaise lasting several months, toward the end of which she became aware of a "peculiar" sensation in the right hand, which extended somewhat up the right arm. At the early period, notwithstanding this sensation, she could use the hand "quite well." For nine months this sensory sensation was the only symptom. Then she became aware of defective appreciation of the size, form, and weight of objects touched by that hand, and somewhat later the astereognostic and baric sense were found to be defective. Tactile sensation was defective as far as the elbow. Afterwards the fingers and hand became stiff, though she could "make them move." A slight spasm was found in them, and almost coincidentally the muscles of the face and those of the leg on the same side became affected with rigidity.

A year after the preliminary symptoms she had a convulsion described as general, in which she lost consciousness. In it the whole body was described as being arched backwards. Further seizures occurred at long intervals. She was unconscious in them all and the body was arched backwards in the severe ones.

There was a gradual extension of impaired sensory function to the leg and face—apparently simultaneously—though these were not so markedly affected as the arm. At a later stage tonic spasms extended to both leg and face, though in the leg it was more marked than in the face.

During all that period her mentality was clear. She had what she described as a fullness in the head, but no headache. Her sight was good and there was no optic neuritis. She had neither vertigo, sickness, nor vomiting. Gradually the motor phenomena predominated over the sensory, the tonic spasm in the arm and leg became pronounced, especially marked in the former. She could neither walk nor stand. Ultimately, about two years after the onset of the illness, she became unconscious, with involuntary evacuations. At this very late stage the friends consented to operation.

The history pointed to an extensive slow growing neoplasm situated in the deeper parts of the brain, involving the sensory and also the motor tracts issuing from the ascending parietal and frontal convolutions. The degree in which the sensory symptoms prevailed at the beginning of the case, and persisted throughout, indicated the posterior central convolution or its conducting paths as the parts primarily involved, and the convulsive movements which ultimately—occasionally—showed themselves were evidence of extension of the irritation to the anterior ascending convolutions, though the opisthotonic arching of the back described in the convulsion indicated involvement of the parts adjacent to the lateral ventricle.

The neoplasm had to be looked for in the conduction paths of the posterior and anterior central convolutions, the former connected with the lemniscus, the latter with the corona radiata. The size of the neoplasm was so considerable as to involve both these parts.

In this unconscious state operation was performed, a large portion of the brain being exposed to give room for manipulation, the centre of the opening being over the ascending parietal convolution. The relation of the dura to the skull was normal and there were no adhesions to the pia. The brain substance and its pia mater covering were possibly somewhat paler than usual. Otherwise the cerebral surface was normal.

An incision was made into the brain substance in line with the fibres from the sensory arm centre—ascending parietal—so as to divide as few of them as possible. At the depth of an inch from the surface the instrument came in contact with a firm neoplasm markedly different in consistence from that of the surrounding brain. Further investigation showed that it was an elongated mass lying obliquely from above downwards, forwards, and inwards (mesially) toward the base, traversing the fibres passing toward the optic thalamus, and involving those of the corona radiata.

The lateral ventricle was freely exposed (a gush of brown-coloured fluid accompanying the opening), the neoplasm involving the external wall and being adherent to the choroid plexus, from which it had to be separated by ligature. It probably interfered by pressure with the internal capsule. It was difficult to remove, requiring, as many of these deeply seated tumours do, delicate manipulation, restraint of force, guided by intensive tactile sense. Several times during the procedure the pulse and respiration gave ominous warnings. For ease of manipulation in the confined space and to lessen the disturbance to the brain tissue during removal the tumour was divided into three pieces, gently raised, and its vascular connexion ligatured. These three pieces measured, after hardening in spirit: first piece, 2½ by 1½ in.; second piece, 2½ by 1½ in.; third piece, 1½ by 1½ in.

It was seen to consist of a fibro-endothelioma with slight encapsulation, some of the cells being larger and suggesting beginning of malignancy.

The external parts were carefully replaced. Owing to the fact that the greater part of the manipulation for the removal of the tumour had taken place in the brain substance, the pia mater investment being left intact, and also to the fact that the removal of the tumour mass had relieved the tension, the edges of the wound in the pia mater came into close apposition like a linear scar—a great point in the prevention of cicatrises becoming adherent to the dura. The dura mater covering was also ample and was carefully readjusted.

After the operation the breathing, which had previously been stertorous, became normal. Four hours after the patient awakened from sleep and it was found that she had recovered consciousness, asking where she was and how she had come into the nursing home. Her curiosity was gently satisfied, but she was not encouraged to make further mental effort at that time. She had long sound sleeps—the first satisfying sleeps she declared she had had for many months. Along with the restoration of consciousness, continence was restored.

Two weeks after, the tonic spasms of the leg had passed off, and three weeks afterwards she could lift her lower limb, and the function thereafter fairly quickly returned. The tonic spasm of the face disappeared. The tonic spasm of the hand remained, and though this lessened in time, the degree which remained, taken along with the defect in tactile sensation, was such that use could not be made of that hand for delicate manipulation. The astereognostic and baric sense were diminished. The patient was, however, able to use a stick in that hand to steady herself in walking.

After the operation her general health improved so rapidly and she felt so well that it was with difficulty she could be persuaded to remain in bed until it was deemed prudent to allow her to rise. When she did rise she was able to walk without assistance, and soon her agility in walking was marked. She could walk several miles very rapidly without fatigue. Though the defect in the hand remained permanent, she entered into and enjoyed life to the full for twelve years. Her mental powers were unimpaired. She remained clear-headed and took an active part in entertaining her friends and in sustaining conversation.

She afterwards died from an acute attack of appendicitis with general peritonitis.

It is difficult to make certain as to where this tumour originated. The sensory symptoms would point to the conducting fibres from the ascending parietal convolution. The elongated tumour itself formed part of the external wall of the left lateral ventricle, from which it extended downwards toward the base and upwards toward the vertex. The attachment to the choroid plexus was intimate. It did not grow from the membranes over the vertex, as it did not even involve the cerebral cortex on the surface.

Tumours of the Hypophysis.

Many such tumours have been reported as having been operated on with a considerable measure of success. Horsley had at an early period four cases. Their interest has been heightened by the growth of knowledge as to the influence of the pituitary body on growth and the production of acromegaly.

There have been four cases in my experience in which the pituitary body was diagnosed as being involved. Two of these were not operated on: one on account of the general weakness of the patient, the other as the progress was slow and the symptoms so slight that operation was not advised.

One of the cases operated on was a fibro-adenoma growing from the hypophysis which had caused absorption of the sella turcica, as seen by x rays—the absorption taking place principally forwards toward the frontal lobe. The patient had a degree of bilateral temporal hemianopsia, unilateral loss of smell (anosmia), and severe frontal headache. The tumour was removed by the temporal route and the patient made a good recovery. Though the slight degree of acromegaly which was present before the operation did not seem to have been much relieved, there was, however, no increase after the operation.

The other case was of a peculiar type—a fibro-cellular tumour or bundle of tumours, of much elongated polypoidal form, springing from the membrane of the hypophysis and involving its substance. The radiogram showed much destruction of the sella turcica forwards and downwards. The sense of smell was absent on the left side and it was defective on the other; the sight was so defective on the left side that hemianopsia could not be made out, though hemianopsia was present on the opposite side. There was proptosis of the left eyeball, evidently from pressure in the orbital cavity. Patient complained of a constant heavy feeling in the left side of the brow and pain in the left eyeball and over the supraorbital nerve distribution. There was a slight degree of acromegaly: the hands and the lips and nose were thick.

The operation in this case was through the fronto-temporal route. On opening the dura and lifting the frontal lobe, what seemed at first to be a single tumour was exposed, but on attempting to remove it the mass separated into a series of polypoid growths with their bases forwards, lying in line with the olfactory lobe. The longest of them measured 0.00 inch and three-quarters, the shortest one and a half inches. The breadth of the broadest part was about half an inch. They were deep red in colour and vascular and somewhat firm to the touch. There was a depression in the frontal lobe in which they lay. Four of these elongated masses within the subdural space, when elevated or turned aside, showed a fifth one, the base of which had softened and thinned the dura and made a depression through the orbital plate of the frontal by which it exercised pressure on the orbital cavity. The bone under this growth was dark coloured and vascular. The attenuated pedicles were attached to the membranes of the hypophysis, but also involved the tissue of the gland, a portion of which had to be removed with each. Free bleeding ensued from the veins of the cavernous sinus during and after removal, which pressure arrested.

The patient made an uninterrupted recovery. The hemianopsia and anosmia disappeared along with the pain in the head. He lost the appearance of acromegaly, though part of this might be due to the general thinning of the whole body. He lost flesh and weight, but remained healthy.

Polypoid growths are much more likely to arise in the sphenoidal cells, and, *a priori*, when growing from the membranous covering and body of the pituitary, one would have expected them at least to have invaded the sphenoidal cells in process of growth. This, however, they did not do in this case.

Points regarding the Subdural Space.

Questions have been asked, especially by foreign colleagues, as to what were the essential elements in brain surgery that promoted success, and how it was that pyogenic invasion of the brain in the form of brain abscess would be overcome. It is apparent that one must have an intimate knowledge of the brain and its function—its anatomy and physiology—and thereafter observe the rules whereby one may gain access to the structure with the least possible damage. The anatomy of the brain must be taken in relation to its envelopes, the head as it is normally; and not the soft contents of the cranium, separated from supports, lifted apart and altered in form by being laid on a flat surface.

As it is leptomeningitis that is the most fatal complication in abscess of the brain, attention to the pia arachnoid and the subdural cavity is necessary.

Not so long ago the peritoneum was supposed to be inviolable; its opening was to be avoided on account of peritonitis, which ensued from the entrance of organisms. Now, with asepticity, that problem has been overcome, and the peritoneum is invaded daily without evil consequences. The pleura likewise was not to be opened, as the physiological dogma of the day taught that the lung was only kept in place through atmospheric pressure, and to open the pleural cavity was to induce instant collapse of the lung. A different view of the physics of the lung recognized that molecular cohesion

—or surface tension—between the two layers of the pleura is the main factor in maintaining the lung in full expansion, and after the two layers have been separated, while performing operations on the lung, the aid of this force may be relied on to restore the lung to its normal state of expansion. So that, by making use of this force, operation on the lung can be freely undertaken, without resort to special apparatus.

The physics of the brain and its meninges are also worthy of attention, especially by those who desire to invade the subdural cavity—as anyone must who is going to perform an operation on the brain.

Doubtless everyone knows the elemental anatomical facts regarding the cerebral coverings and their relations, but do we fully realize and act upon them? We know that there is a subdural space, but there is a confused idea that the spider has spun its web with many attachments between the dura and the surface of the brain.

The arachnoid scarcely exists as a distinct continuous detachable membrane over the surface of the cerebrum, but rather as a few sparsely distributed cobweb strands of connective tissue bridging the surface of the sulci, and from which a few detached strands may occasionally be seen during life suspending the blood vessels on the surface of an oedematous brain. Therefore one agrees with Hensle* rather than with Biehler in his views of the arachnoid. A slight extra separation of the pia from the dura by fluid, such as external hydrocephalus or a subdural haemorrhage, disrupts many of the cobweb strands, and a clear subdural space exists, extending from the vertex to the base, and from that to the spinal cord. When this free subdural space obtains, a subdural haemorrhage occurring on the vertex would be free to spread in a thin layer over the surface, and to envelop the brain, extending to the base, and might penetrate into the spinal canal and prove fatal by pressure on the respiratory centre. That this can take place with serious results the following record will show.

On one occasion when starting on a professional visit to the country, and having just left myself time to catch the train, I was taking a ticket at the booking office when I became aware of the people in the queue laughing at some remark which I had only partially caught. It was repeated, however, by an importunate man, who, addressing me, demanded that the "Professor should open his head." I had to go quickly to the train, and on reaching my carriage found that the man had followed, repeating his request. The officials, hearing him make the strange request and seeing that his equilibrium was not quite certain, were keeping him back from the carriage. I had, however, time to look at him for a moment and saw that he was ill—dazed and having inequality of the pupils. I had just time to take out a card, writing on it "Admit patient, Royal Infirmary, urgent, examine head, possible operation," asked the officials to put him into a cab and send him up, when the train departed.

On returning from the visit five hours afterwards I went straight to the Royal Infirmary and found the house-surgeon, who told me he had been coming to tell me the patient was ready for operation when he was overtaken by a nurse to say that the patient had just died suddenly.

Previously they had noted wide dilatation and fixation of the left pupil, and a hemiparesis of the right side of the body. He had given them the history of having fallen ten days previously and struck his head on a projecting stone. He had never, at that time, been unconscious, but suffered from great pain and feeling of weight in the head.

He had gone to his work—that of marble cutter—the following day, but was put off at dinner time as the foreman stated he was not cutting his lines straight. He was advised to return when he was "sober." The same thing happened when he again returned to work the next day, when he was dismissed. He stated that he was perfectly sober and had not been drinking. During the time he was being prepared for operation, not desiring to lie down, he sat on a chair, stating that he was easiest when he was leaning forward with elbows on his knees and his hands supporting his head—that he had sat that way since his injury and had never been in bed.

He afterwards went to bed in the ward, where he lay without a pillow, half prone and with his forehead over the side of the bed looking downwards. In this posture he was at ease and fell asleep. Shortly after his position was altered and he lay on his back, immediately after which his breathing

became stertorous, his respiration suddenly ceased, and he died.

At the autopsy a subdural haemorrhage of large extent and fully a quarter of an inch thick was found, which had extended from the posterior part of the frontal lobe all over the external surface of the cerebrum, including the occipital lobe. This was semi-coagulated. It was seen that the clot, which had been somewhat adherent to the walls of the subdural space, had recently slipped backwards to the extent of an inch and a half from its original position, leaving vestiges of its presence in the shape of minute clots adhering to the meninges to mark its former place.

The semi-solid clot, which had slipped and shifted its position from the vertex toward the base, had extended through the aperture in the tentorium, crowded the pons and medulla, pressed on the contents of the rhomboid fossa, and arrested breathing. The cause of the bleeding was rupture of the posterior middle meningeal, which had been injured by a fissured fracture which extended from the base toward the vertex without encroaching on the middle ear.

How many times after traumatism does the blood effused into the subdural space spread and gain access to these vulnerable basal parts, especially where the practice obtains of placing an insensible man on his back, gravity thus aiding toward the fatal issue?

During the process of exposing the brain for the removal of neoplasms and while pushing aside the external coverings, if haemorrhage occurs into the subdural space it is serious, and the more so if, after wounding a large surface cerebral vessel, the free opening of the skull and its membrane is delayed. For this reason, among others, the ordinary trephine is seldom used, a large osteoplastic flap being raised instead. The dura is opened from the centre of the exposed surface, care being taken to do so without injuring any of the vessels of the pia mater. In this way a clear view is obtained of the fresh normal surface of the brain without obscuration by blood. The delicacy and tenuity of the superficial cerebral vessels is so great that they abrupt on very slight traction, and in order to ligature them successfully one ought to have previous practice, by ligaturing the strands of a suspended cobweb, and so realize how big and how forceful the fingers are. One has also to educate oneself to refrain from ligating any vessel that may be circumvented, as anaemia of even a minute area of the brain may lead to degeneration and perversion or destruction of its function.

Entrance of Pyogenic and Pathogenic Organisms.

Pyogenic organisms introduced into such a cavity would be disseminated along the loose strands of connective tissue of the pia arachnoid with great rapidity, so that in a few hours the whole pia-arachnoid would be diffusely affected and the whole cerebro-spinal system involved. When the pia is affected the whole cerebral cortex is involved.

Though this is well recognized in the steps taken to secure asepsis from without, is it equally carefully observed when removing pyogenic or pathogenic organisms from within a walled-off area in the brain already guarded by defensive adhesion? Does the operator follow the rules he would observe were he about to deal with a localized abscess bound off by adhesions from the general cavity of the peritoneum? Presumably no one would care to open such an abscess through the healthy peritoneum and thereby expose the general cavity to invasion, even though it might be the easier route to follow.

In the earlier periods it was believed that abscess of the brain was pyaemic, and therefore regarded as hopeless.* Even were the abscess of the brain pyaemic in origin and located in the white substance it could be dealt with surgically, provided provision were made for the uncontaminated preservation of the subdural space by preventing pyogenic matter from coming into contact with the soft membrane and setting up a leptomeningitis. Therefore adhesions, natural or artificial, must be sought before opening the abscess through the subdural space.

It has been recognized that the majority of uncomplicated brain abscesses—such as those occurring in the temporo-sphenoidal lobe—form by continuity of invaded tissue directly from the point of origin, and soldering of the meninges occurs in process of, and in many cases prior to, the formation of the abscess. There is thus a route or pathway of invaded

* Hensle describes the arachnoid as a connective tissue of extremely loose make-up.

* At an early period it was said by a very eminent member of our profession that it was useless to attempt removal of a brain abscess as they were all pyaemic and would all prove fatal. Is this belief quite dead?

tissue between the point of origin and the abscess round which nature attempts to form a defensive barrier.

In endeavouring to relieve the contents of the abscess one must keep within the limits of the adhesions by traversing the parts through the affected area from the original focus to the abscess itself. The evacuation would then be accomplished under favourable conditions—as leptomeningitis would be unlikely to occur. It is doubtless more difficult to follow this tract to the abscess than to open directly through the skull, and the latter gives more room for manipulation. But in adopting this course one is opening the general subdural cavity and exposing it to contamination unless one affects the closures of the space by soldering the membranes artificially before proceeding to evacuate. As leptomeningitis is the most fatal complication of brain abscess it is of paramount importance to prevent its occurrence.

Subdural Space: Leptomeningitis from Violent Vibration in Opening the Skull.

The method of removing the osseous covering in order to gain access to the abscess is of importance as, if in so doing vibration of a rude kind is produced, the spicules of ossified bone at the seat of disease, being bathed in pyogenic matter, are apt to penetrate the soft membranes with their jagged edges, and to inoculate the pia arachnoid and set up leptomeningitis.

Instrumental work is done more gently without producing violent vibration, such as the surgical burr, which may be held lightly like a pencil in the guiding fingers, remove the bone in minute flakes without injuring the soft parts.

Though having used the osteotome and mallet in performing thousands of osteotomies on the bones of the extremities, it has never been used by me on the skull; as it was feared that the violent impact and vibration occasioned thereby would be detrimental to the delicate contents. Even for the removal of cerebral neoplasms the violent vibration in opening the skull by chisel and mallet must in many cases be detrimental to the softened cerebral substance and the enlarged thin-walled blood vessels in the vicinity of the tumour or abscess.

Post-operative Adhesions between the Brain and its Membranes: Can they be Prevented?

Having removed the neoplasm from the brain with as little interference of its structure or its blood supply as possible, one has to endeavour to mitigate the damage to the surface of the brain and to restore the subdural space to its normal conditions.

Can adhesions between the brain surface and the dura or skull itself be prevented?

In the abdominal cavity adhesions give rise to considerable and sometimes serious trouble. In the intracranial cavity adhesions between the pia mater or the nude brain and its rigid envelopes may mar the subsequent results of the most brilliant operation. By the constant dragging of these adhesions on the brain tissue extensive degenerative processes may be set up, giving rise to fresh brain areas being involved which may prove fatal. Normally the brain floats in its waterbed and is contained within its covering like a specimen in a bottle which has been specially shaped to the form of the specimen; this economizes space and fluid. Its surface is not adherent to any part of its fixed coverings, though attached basally by certain nerves. This allows of accommodation to the varying conditions of the brain in expansion and contraction, in response to vascular conditions and to the varying positions of the body. When the brain becomes fixed by an adhesion to the rigid wall two things happen: the motor cortex at that point does not function properly, and secondly, there is a dragging at the point of fixture and for a considerable distance beyond, and as this dragging is repeated with varying conditions of the brain the mechanical interference tends to produce degeneration in the white substance as far as the strained brain fibres extend. This may be mitigated by guarding against sudden changes in cerebral vascularity and quick alterations of posture; the patient himself, realizing his altered condition, aids in these directions.

It is very desirable to prevent such anchoring of the brain, or if this be impossible to mitigate the evil by making the adhesions as long as possible, so that there would be a little play or yield in the cable; the brain would not then be so suddenly checked in response to its varying conditions.

In endeavouring to prevent adhesions one misses the

arachnoid membrane. The spider's web would be useful to cover a wound in the brain and to intervene between the cerebral surface and the dura. Very occasionally by diligent search a tangible portion of the web has been found sufficient to cover a small surface. If one only had in the brain coverings an apron like a modified omentum, which is of so much service in preventing adhesions between parietal and visceral layers in the abdomen, it would answer the purpose admirably. On one occasion a thin portion of omentum was used to cover such a defect between a large nude portion of the brain and the dura. It was carefully prepared and easily applied, accommodating itself to its new situation, and apparently served its purpose, as this patient had no after-evidence of adhesion. The specimen was taken from a redundant omentum, removed during a radical cure of hernia. One of the most easily procurable substances is blood clot. It is bland, mild, and accommodating, and allows sufficient time to elapse for the healing of the wound in the brain before complete absorption takes place. Gold-foil is also of use, but it does not become absorbed and sometimes seems to occasion irritation. On one occasion a portion of gold-foil had to be removed by subsequent operation as it had occasioned irritation and slight spasms.

Whatever method is adopted the main point is to secure the closure of the defect in such a manner as to refloat the organ and to restore the free flow of cerebro-spinal fluid. Although brain anchoring does produce serious effects it does not affect all equally seriously. Some who have been operated on at an early period of the new era of brain surgery and had the misfortune of having a certain degree of brain anchoring, have lived many years of useful life—one patient over thirty years. They exhibited slight defects, such as vertigo and sickness on sudden changes of posture, such as stooping and then rising quickly. One had in addition occasional faintness, slight unconsciousness, and convulsive movements of the muscles of the opposite side, which only lasted a few minutes. Games such as tennis could not be played except with restraint. One patient had more serious fits and mental confusion whenever he took influenza. He had to remain in bed while the attack lasted. Otherwise he lived for over twenty years and did good work. He is still alive and at work.

It has been advised to leave the large aperture in the skull open to obviate some of the effects of cerebral adhesions, and though benefit in this direction may ensue, other more serious disadvantages obtain. The brain is never so happy as when at home contained within its own normal case. The restoration of the osseous covering by reimplantation of bone has long been practised by me.

It is hoped that by drawing attention to these simple details the prospects of recovery may be improved and the subsequent troublesome sequelae avoided.

Tubercle of the Brain: Can it be Advantageously Operated on?

Regarding the most frequent invaders of the brain, syphilis and tubercle, one is seldom called on to afford relief for such lesion by operation. They are diseases due to organisms which in the former are always and in the latter are apt to be generalized throughout the body. Though these diseases are amenable to medical treatment, yet both produce neoplasms which undergo degeneration and often caseate, and once such a necrotic neoplasm forms medicaments circulating through the blood stream, though they may affect the living tissue in their periphery, cannot penetrate into the dead mass, and therefore it remains. Though it might be otherwise quiescent, it presents itself in the brain as a foreign body exercising pressure on the delicate brain structure to its detriment, producing focal irritation or generalized symptoms according to its extent and distribution.

Tubercle is often meningeal, and in the form of acute diffuse cerebro-spinal tuberculous leptomeningitis so impresses itself as a hopeless condition which at least no operative measures can permanently relieve, that this picture overshadows other forms of tubercle in the brain which are apt to be placed in the same category. Yet tubercle is not always meningeal, and even when it is it may be localized.

Tubercle may be deposited primarily in the brain substance, in the white matter, where the finer vessels penetrate, and there cause concentric nodules which grow occasionally into very large tumour-like masses. Some of the largest solid neoplasms in the brain are tuberculous, and from their size threaten life and do kill from pressure—mainly, if not alone. That is important, as in these cases there is no

meningitis or evidence of dissemination, and therefore had the bulk been removed relief and probably cure could have resulted.

When tubercle is deposited in the fine vessels of the white matter of the brain primarily, if near the cortex, the extension of the nodule peripherally may involve the meninges and set up a secondary leptomeningitis if soldering of the membranes had not preceded and prevented the invasion of the subdural space. This is a second source of danger from the primary cerebral tuberculous nodule and another reason why such nodules would be better removed were that possible, with a reasonable margin of safety and the prevention of dissemination. When possible one ought to secure adhesions of the membranes before removal of such foci.

A number of these deep-seated tuberculous neoplasms in the brain are single or solitary; this has been proved at the autopsy. Some of those that have been removed from the brain during life were apparently solitary, no others having signalled their existence, and the patient has either lived for years or has died from other causes, or from tuberculous attacks in other parts of the body without signs of recurrent cerebral involvement. Liquefaction of such tuberculous neoplasms occurs and forms one of the so-called "encapsulated abscesses" containing the characteristic white creamy emulsion-like fluid. The histories of many of these point to their long duration—many years, some a lifetime. If there be an exit through the meninges and skull through which they may empty themselves, it is possible they may do so at intervals over long periods, and when such an exit exists other organisms may enter. The pyogenic organisms, finding in the tuberculous emulsion rich pabulum, readily invade the cavity and set up therein an acute pyogenic action. In one instance the pyogenic organisms invaded the periphery of the encysted abscess, destroying the brain extensively in its circumference and forming a sea of pyogenic pus, in which the encysted abscess, containing its characteristic creamy tuberculous liquid, was seen floating intact and from which it was removed by operation.

One of the patients from whom an encysted tuberculous so-called "abscess" of the brain was removed thirty-five years ago is still living and at work. Presumably this was a "solitary" tuberculous brain lesion.

When tuberculosis invades a localized portion of the brain the cortex of the strands therefrom are involved and sensory or motor impressions may result. When localized to restricted areas it may give rise to sensory or motor symptoms and to epilepsy of a Jacksonian type with the usual phenomena. Removal of the affected portions stops the epilepsy and prevents dissemination of the tubercle.

Tuberculosis occurring under the tentorium cerebelli, where it forms formidable neoplasms, presents quite another problem. Here the pressure of the growth gradually persists until it affects not only the vital centres—the respiratory and cardiac—but is far-reaching in its consequences. The whole cerebrum is benumbed from the distension of the ventricles with cerebrospinal fluid and the production of oedema of the brain. The eyesight is involved by the induction of optic neuritis and nerve atrophy which destroys the sight. In the later stages the patient presents a deplorable aspect—the earthly pallor of the face, the complete atony, scarcely able to move a limb, the disturbance of equilibrium so marked that while lying flat in the bed heaves, the furniture, the nurses, and the ward gyrating like a ship in a tumultuous sea. As the patient lies groaning with pain, headache, vomiting, scarcely able to breathe, with slow pulse, he completes a picture of agonizing misery which compels relief. He is virtually being crushed to death.

The free removal of the osseous envelope aids; the full opening of the dura affords much and instantaneous relief, which is increased by inducing the neoplasm to escape from the cerebellar contents. To this end the opening may be extended over the whole cerebellar fossa, the strong girders being left intact—and even, if need be, the opening may extend into the foramen magnum at its posterior aspects. This gives speedy and effective relief to pressure on the medulla, and the cut edges of the foramen are guarded by that portion of the cerebellum which normally dips through the foramen magnum into the upper portion of the spinal canal, and which does so to a much greater extent when the cerebellum is under severe pressure from abscess or neoplasms.* When a patient after an operation of this kind has recovered from the sleep of exhaustion induced by his long suffering and is able to appreciate that he is actually free from his terrible ordeal with all its pain, vertigo, and sickness, the look of relief—the smile that lights his face—is worth much!

It is, however, at the very early period of invasion of the cerebellum that the diagnosis is of so much importance, as the disease could then be removed by a smaller operative procedure, and the prognosis would be much more hopeful; and even were the operation unsuccessful in affording permanent relief, it would prevent the patient from undergoing the crushing agony. At the early period, however, the diagnosis of tubercle in the cerebellum is difficult, and sometimes months elapse—sometimes many months—before symptoms occur sufficiently obtrusive to arrest attention. As these neoplasms form frequently in children, some of school age, their early indications are insidious and are often misconstrued. They occasionally occur in bright children who have done well in school, who after a time cannot maintain their place, appear careless and negligent, and are sometimes treated on this assumption. Later they become listless, dull, and apathetic, and no longer engage in the vigorous games they previously enjoyed. The tumour is in the cerebellum, yet it is the cerebrum that affords these early symptoms. The cerebrum has become affected by the distension of the ventricles and involvement of the optic tract. The differential

Tuberculous neoplasm in brain, showing the results of its presence.

percussion note reveals the presence of the distended ventricles.

In one such case—one of many seen—the wise teacher, instead of punishing the boy, sent him to the father, relating the change in his school behaviour and his seeming loss of interest in his work. The parents could not find anything the matter, but brought the boy to me for examination, as they said if there were nothing wrong with him mentally or physically they would know how to act. Much to his astonishment, the father was told that the boy was suffering from a form of tumour, probably situated in the posterior part of the brain, which would eventually declare itself in

* The fact that the cerebellum dips through the foramen magnum normally and protects the medulla was alluded to by me in 1839, and was thereafter illustrated in the *Atlas of Head Sections*, published in 1892. Professor Adami of Vienna had expressed disacreement and suggested that the method of preparation of the specimen—that of freezing—had expanded the brain and caused the extrusion. The freezing, however, was effected from without inwards, which would have a contrary result—if any. Had the expansion from within been so great, the tentorium would have been overextended or burst, whereas it remained intact and normal; there would have been protrusion of the eyeballs, whereas they were rather contracted; and where the cerebellum protruded the medulla would have been equally affected, whereas it was found in its normal relations and size. Professor Symington, from independent and various methods of investigation, other than freezing, verified the observation that a portion of the cerebellum does normally pass through the foramen magnum into the upper part of the spinal canal.

certain directions unless it were relieved. Although the boy thought he could see quite well, yet the visual acuteness had diminished; there was slight turgescence of the optic discs. Though he had no ataxia at the beginning of the examination, it became distinct after his pupils had been dilated with homatropino, and the accommodation was suspended. He was aware of not being so sure of his movements in the dark as he used to be. The percussion note over the head—the pterion—revealed the presence of considerable fluid in the ventricles, and that, along with other phenomena, explained the cerebral symptoms.

The note elicited on percussion of the skull has been used by me since the early seventies in aiding in the determination of certain pathological conditions which alter the physics of the cranial contents, especially those of the distension of the lateral ventricles. Since then it has been employed regularly as occasion presented, and it has been found of particular use in children and in those whose skulls are sufficiently thin to vibrate on percussion. In such it has been found a valuable adjunct to other means of diagnosing intracranial contents physically. In this country it is only occasionally that one sees mention of its use, but it is now methodically practised abroad—in some quarters as a regular routine of the examination—and it has been found reliable. It is particularly useful as it is an early symptom often elicited when the signs of cerebellar neoplasm are still doubtful or in need of support by further evidence. Its presence has often determined the further search for causal neoplasms whose symptoms afterwards slowly evolved.

In Germany it has sometimes been described as the "cracked-pot sound"—this it is not. The "cracked-pot sound" is seldom heard on percussion of the head. In an experience of many injuries of the head, the genuine "cracked-pot sound" has only been heard by me on six occasions—at long intervals the one from the other. In one case, where it was very pronounced on percussion of the head, it was found at *post-mortem* examination that there was a fracture of the skull completely circular—passing through the base, including both petrous bones, and meeting over the vertex—the skull being completely divided into two halves. One does not find the "cracked-pot sound" except where there is an extensive fracture of the skull. The differential percussion note referred to, which is found where the lateral ventricles are distended, is generally best elicited by percussion over the pterion, and it alters its pitch according to the position of the head—the side that is undermost giving the clearer hollow note. It cannot be found in a hydrocephalic head where the bones of the skull have not been united.

Abscess of the cerebellum when small and limited is easily removed, the difficulties lying more in the early diagnosis of the location of the abscess than in the removal of it once the diagnosis has been made. When due to extension backward or pyogenic processes from the middle ear the location of the infected tract in the vicinity of the knee of the sigmoid sinus is so constant that it aids in determination of the point of access to the pus.

In large abscess of the cerebellum, however, pressure results ensue, though the pyogenic process being much more acute the pressure effects on the adjacent structures are intensified by the inflammatory action with its attendant oedema—hence the respiratory difficulties threaten life occasionally with tragic suddenness. Though usually there are premonitory signs of respiratory involvement sufficiently in advance to afford time to rectify the condition by operation, yet sudden access of oedema may precipitate a fatal issue. In four instances of large cerebellar abscess, so quickly had the respiratory difficulties ensued that operation had to be performed by me while artificial respiration was being carried on. In one of these a patient who had become unconscious before admission to the hospital had only reached the ward when his respiration ceased. Artificial respiration was commenced at once and continued until operation could be performed. The whole operation had to be conducted simultaneously with the performance of artificial respiration, and as the respiration was paramount the position of the patient had to be arranged to accommodate it. Consequently the operation had to be performed from below. No anaesthetic was given as the patient was unconscious. On reaching the abscess two ounces of pus escaped, and shortly after the first spasmodic respiratory gasp occurred, which was repeated, and gradually the automatic respiratory movement was re-established—much to the relief of the staff. While the house-surgeon and nurses, who had just been relieved from their arduous and fatiguing work of prolonging artificial

respiration were still on the alert with drawn faces and strained anxious expressions, watching the man whom they had such great difficulty in rescuing from the brink, the patient recovered consciousness, and seeing his strange surroundings and the anxious theatre staff exclaimed, "What is all this damned fuss about?" It had a startling effect on the astonished staff—the unseeing eyes, which had been open all the time, suddenly saw! The removal of the pressure and the inflammatory oedema from the respiratory centre situated on the posterior part of the rhomboid fossa had relieved the cardiac and respiratory centres and the consciousness was restored by the relief of the ventricular pressure on the brain.

The Suprameatal Triangle.

The suprameatal angle above and behind the ossous auditory meatus with its apex forwards was proposed to be used by me as a guide or landmark to the position of the mastoid antrum. It was found that, when converted into a triangle by dropping a base line parallel with the posterior part of the external auditory meatus and operating within that area, the mastoid antrum could be safely reached without encroaching on the knee of the sigmoid sinus or endangering the facial nerve. The mastoid antrum is the key to opening the mastoid in gaining access to pyogenic lesions of the temporo-sphenoidal lobe. It is through the tegmen tympani and auri that abscess in the temporo-sphenoidal lobe of the brain may be reached within the area of the safeguarding adhesions, and through the posterior wall of the antrum that access may be had to the sigmoid sinus and to the adherent membranes in front of the cerebellar abscess.

Later experience in using this suprameatal angle as a guide has been extensive, and has always proved to be reliable. It has been advised that in perforating through the mastoid so as to strike the antrum the drill should be directed slightly upwards and forwards, and there are cases where this upward direction would be necessary, owing to sclerosed bone pressing the antrum upwards.

Extended scrutiny of the skulls of many nationalities, ancient and modern—from the pigmy of the African forest to the higher types of civilization—has been made, since the suprameatal angle was proposed as a guide or landmark, and it has been found that the suprameatal angle has been universally present, though in some specimens it has been more distinct than in others; not only so, but in some of the higher apes (whose skulls have been examined) the suprameatal angle is also found. Through the courtesy of Sir Arthur Keith, Professor of Comparative Anatomy in the Royal College of Surgeons, several skulls of chimpanzee which had the suprameatal angle distinctly marked were sectioned—through the angle—and the sections were found to pass directly through the mastoid antrum. In one specimen of the gorilla, which had not such a distinct suprameatal angle, the section disclosed a small antrum surrounded by many smaller cells.

Doubtless the dome of thought ought to be left inviolate. It was built that way, but occasionally rude traumas and peccant matter invade the sanctuary and have to be followed and removed.

It has been said that the brain stands much handling. Possibly! One cannot open the skull as a box and rummage until the object is found. The accuracy of diagnosis is of paramount importance. Many errors of diagnosis may be rectified by exploratory incisions in the abdomen. This is much more difficult in the brain.

The more one sees of the intricate, delicate structure, the greater the reverence one entertains for it, and the less one is inclined to disturb its arrangements or to interfere with its function. When it does require to be touched it ought to be with the greatest gentleness, by an acutely sensitive finger, carefully trained and guided by the blessed gift of memory of tactile sensations, to which each new impression may be quickly relegated, grouped, and correlated in ordered sequence. When neoplasms have to be removed therefrom the endeavour is to do so with minimal disturbance of brain tissue. It is for this reason that the impetus received from the intrinsic cerebral pulsations are utilized to aid the extrusion of blood clot or neoplasm through the incision in the brain once adhesions have been loosened, as, though this method takes more time, it does less damage.

Cerebral surgery has been the means of adding to and confirming the knowledge of brain function in man, especially of the regions of the cerebral cortex other than motor, to which experimentation on the lower animals can with difficulty contribute. It has laid bare physical lesions in the cerebrum

producing mental aberration, and, by the removal of the lesion and the restoration of cerebral function, has thereby proved that the presence of the lesion was the cause of the perversion of function. In a sense some of these lesions produced in the brain of man may be regarded as experiments carried out by nature with a delicacy, accuracy, and refinement which no human experimenter could equal. Surgery of the brain has its limits, but these have not been reached. There is still a large field for careful observation and accurate work.

A period of growth in cerebral surgery has been touched on. It is hoped it may be concluded that the introduction of cerebral surgery with its scientific basis has been justified. It has been the means of saving many lives, and by removing the "blot" upon the brain—or by unravelling a tangled skein—has brightened existence.

Proceedings of Sections.

SECTION OF INDUSTRIAL DISEASES AND FORENSIC MEDICINE.

PRESIDENT'S ADDRESS.

BY

JOHN GLAISTER, M.D., F.R.F.P.S. GLAS., D.P.H. (CAMB.),
F.R.S.E.,

Regius Professor of Forensic Medicine and Public Health, University
of Glasgow; Specialist Medical Referee in Industrial Diseases
for the Counties of Lanark, Ayr, Renfrew, Dumbarton, and Stirling.

THE conjunction of the subjects of forensic medicine and industrial diseases in one Section may seem, to some at least, to be incongruous, but when it is remembered that forensic medicine is the application of the science of medicine to the purposes of the law, and that probably no Act of Parliament has ever given rise to so much litigation as the Workmen's Compensation Acts, the incongruity at once disappears.

The subject of compensation to workmen for injuries and for accidents in the form of industrial diseases has found a place in some textbooks treating of forensic medicine, but hitherto forensic medicine has been considered chiefly from the standpoint of the criminal law. It is, however, of importance that the medical student should know something of the purport and administration of the Compensation Acts in view of his possible appointment in the future as Certifying Surgeon and, later, as Medical Referee. It is necessary, therefore, that he should begin his medical career equipped with some knowledge particularly of industrial diseases, looking to the fact that the chief populous centres of the country are hives of industrial operations.

At the Seventeenth International Congress of Medicine, held in London in 1913, I read a paper in the Forensic Medicine Section—published in the *Congress Transactions*—on "The Workmen's Compensation Act, 1906, and its Operations in Great Britain." In that paper attention was drawn to the principal provisions of the Compensation Act, 1906, and of the Employers' Liability Act of 1880. Some consideration was also given to industrial diseases. The former Act came into operation in July, 1907, and the first completed statistics relative to its operation were published in 1909. This paper was illustrated by a series of fifteen tables collated from the returns of 1910 and 1911.

Dealing for the moment with forensic medicine, two subjects will now receive attention.

From time to time the question has been openly discussed: Whether the time has not now arrived for the inclusion under one group-subject of all matters which involve the application of the science of medicine to the purposes of the law, such as National Health Insurance, the Compensation and Employers' Liability Acts, and those portions of Public Health law briefly comprised under the headings of Nuisances, Unsound Food, and others relating to medical knowledge as applied to the law, with the title of State Medicine.

Much can be said on both sides of this subject, but the conclusion which may judiciously be come to at present is, in my opinion, that the time is not yet ripe for such general inclusion. It has to be borne in mind in this connection that the Workmen's

Compensation Acts and the National Health Insurance Acts, which at their institution were revolutionary in principle, have not yet been established sufficiently to warrant a sudden change in the manner indicated.

Another subject canvassed at present is: Whether the teaching of forensic medicine to, and examination in that subject of, all students of law as well as of medicine should not now be made compulsory before they are recognized as qualified to practise their profession.

The regulations of the General Medical Council demand that medical students shall be taught and be examined in forensic medicine or, what is merely another designation, in medical jurisprudence. In Scotland it can be claimed that the subject receives its fair share of attention in the medical curriculum, and also in the examinations of the universities and medical corporations, but doubt may be expressed whether the same attention is being given in certain examinations in England.

In view of the fact that any general medical practitioner may suddenly be confronted with a set of circumstances which demand of him an accurate knowledge of medico-legal matters, and may thus become an important witness in the after-proceedings in the case, it is essential for the protection of the lieges and in the detection of crime that he should be familiar with the subject. Some recent cases do not exhibit that knowledge. Speaking from experience gained from over forty years' work as a teacher of forensic medicine, and from nearly a like period as a medico-legal expert engaged in Crown work, one has to confess that the importance of the subject to the average medical practitioner is not generally recognized. One cannot avoid the conclusion, moreover, that not a little litigation, especially as exhibited in medical evidence, could be avoided by a better acquaintance with forensic medicine. And what is true of the medical profession is, perhaps, still more true of the legal profession. In Scotland and, we understand, also in England the general practitioner in law—the law agent or solicitor—does not require to study nor be examined in the subject of forensic medicine before being admitted to the practice of the law. While this may not be essential for certain classes of legal practitioners—as, for example, conveyancers—it is highly essential for the general legal practitioner who undertakes the work of litigation in the lower courts in cases involving medical matters and medical testimony, as in compensation cases and in criminal work.

In Scotland a candidate for the Bar must study and must have passed in the subject of forensic medicine, but we are not aware of a like compulsion for admission to the Bar in England. While we cannot but admire the ability displayed by barristers for prosecution or defence in criminal cases tried before the higher courts, the feeling remains that previous acquaintance with forensic medicine would have been of advantage. From my experience in the law courts I have long since reached the opinion that the time is more than ripe for the institution of a regulation by the law societies, whose qualifications admit as law agents or solicitors, for the compulsory study of and examination in forensic medicine as part of the curriculum by all candidates.

INDUSTRIAL DISEASES.

I propose to look at this subject retrospectively and prospectively.

History of Compensation to Workmen.

The history of compensation to workmen may be thus compendiously stated: Until 1880 in this country the only legal remedy open to a workman who had sustained bodily injury in his employment was an action at common law against his employer. In 1880, however, Parliament passed the Employers' Liability Act, which modified the common law rules to the workman's interest. But, in an action raised under this Act by a workman or by his dependants, it was necessary to prove that the accident causing injury or death was caused by defects in the plant or machinery due to the negligence of the employer or of someone under authority of the employer. The workman or his dependants was liable to be met with the defence of "contributory negligence" on his own part or of that of a fellow workman, and also of the plea of *volenti non fit injuria*—that is, if the workman agreed expressly or by implication to accept the common risk of employment. This Act, therefore, did not provide a certain, easy, or inexpensive means of obtaining compensation.

In view of the foregoing, certain movements were made by

those in power to amend the Liability Act of 1880, and a bill was introduced into Parliament in 1893, which was passed by the House of Commons, but was abandoned by the Government when the House of Lords preserved the doctrine of "contracting out" in its amendment.

In 1897 the first Workmen's Compensation Act was passed, by which a remarkable change was made in the law relating to master and servant; indeed, as compared with the legal relationships as to responsibility embodied in the Employers' Liability Act, 1880, the provisions were revolutionary, for the Compensation Act imposed on an employer the liability to pay compensation to an injured workman, or to his dependants if the injury proved fatal, quite independent of the question whether or not there had been negligence on the part of the employer or of any fellow workman. This was a new principle established in law for the first time.

In 1900 the second Compensation Act was passed. This differed only from the first Act in that it included agricultural employees as beneficiaries under the law. This Act of 1900 had been in operation for three years when a Departmental Committee was appointed to inquire and report regarding: "What amendments in the law relating to compensation for injuries to workmen are necessary or desirable, and to what classes of employments not now included in the Workmen's Compensation Acts those Acts can be properly extended, with or without modification."

This Committee reported in 1904, and the Compensation Act of 1906 embodied their recommendations. In short, the Act of 1906 codified and extended the Acts of 1897 and 1900.

For the first time, however, in the history of these Acts, industrial diseases were brought within the scope of compensation, and procedure was improved for accidents generally by enabling a county court judge in England and a sheriff in Scotland to summon a medical referee to sit with him as assessor in disputed cases. Moreover, power was given to parties jointly to refer their dispute, as to the cause or extent of the incapacity of the workman, to a medical referee, and a provision in the Act enabled the Secretary of State to confer on committees representative of employers and workmen certain powers for arbitration otherwise conferred exclusively on county courts.

In this year (1906) there was no provision in the United States of America for compensation to workmen enacted by legislation. By 1920, however, no fewer than 42 out of the 48 States comprised in the Union had compensation laws in operation. Each State or province of the British Dominions has an Act for the like purpose. Russia came into line in 1913, and Portugal in 1919. Even in Hawaii, Porto Rico, Cuba, Salvador, and Japan does compensation law prevail. It may be concluded, therefore, that the most of the civilized world to-day has operative compensation laws.

Persons entitled to Compensation.

The Act of 1906 extended the scope of beneficiaries still further than the previous Acts by including practically all persons in employment other than casual workers, all persons employed in the service of the Crown as employer of labour or in any workshop under control of the Government, to masters, seamen, and apprentices to the sea service, and to apprentices to the sea-fishing service, in all vessels registered in the United Kingdom or of any other British ship or vessel of which the owner or manager resides or carries on business in the United Kingdom, and to pilots in terms of Part X of the Merchant Shipping Act, 1894; but the extension did not include members of the crew of a fishing vessel remunerated by shares in the profits or gross earnings of the working of such vessel, nor persons in the naval or military service of the Crown.

The following is an interesting definition of the expression "workman" given in the Act of 1906:

"Workman does not include any person employed otherwise than by way of manual labour whose remuneration exceeds two hundred and fifty pounds a year, or a person whose employment is of a casual nature and who is employed otherwise than for the purposes of the employer's trade or business, or a member of a police force, or an outworker, or a member of the employer's family dwelling in his house, but save as aforesaid, means any person who has entered into or works under a contract of service or apprenticeship with an employer, whether by way of manual labour, clerical work, or otherwise, and whether the contract is expressed or implicit, is oral or in writing."

The Departmental Committee on this Act reported in 1920 that they had arrived at the view that the sum of £250 which formerly included clerical persons in offices should, by reason of the rise in wages of recent years, be raised to £350, since by this cause of risen wages not a few have ceased to be eligible for compensation under the Act.

The 1906 Act was getting into full swing when the great war broke out in August, 1914, and for the next few years its operations were ruthlessly disturbed, so that statistical data for the years of the war can only be given approximately.

The aggregate number of persons within the scope of the Act who were employed in the seven large industrial groups in 1919 was upwards of eight millions (8,359,183), and in 1920 was 8,348,150.

The figures for the years prior to and after the war are shown in the following table:

TABLE I.—Showing the Number of Workmen under the Compensation Act before and after the Great War.

Year.	Number.	Year.	Number.
1910	7,025,074	1914	7,057,111
1911	7,305,997
1912	7,411,005	1919	8,359,183
1913	7,509,353	1920	8,348,150

The fall in number in 1914 is doubtless accounted for by the enlistment of workmen into army service, and that in 1920 by trade depression and other factors.

The monetary cost of compensation to employers of labour has also increased, as the following table indicates.

TABLE II.—Showing the Total Sum paid in Compensation in the Seven Industrial Groups, the Number of Fatal Cases, and the Number of Disablement Cases.

	1910.	1911.	1914.	1919.	1920.
Total sum ...	£2,700,325	£3,056,404	£3,465,351	£4,616,723	£5,978,003
Fatal cases ...	3,510	4,021*	4,216†	3,293	3,531
Disablement cases	378,340	419,031	427,910	355,176	381,956

* Hulton colliery disaster in late December, 1910, accounted for 344 lives.
† Another colliery disaster befell this year.

In 1919 the annual charge for compensation in these seven industrial groups averaged 10s. 6d. per person employed, but the figures varied in the different individual groups. Shipping, for example, averaged 14s. 10d. per person employed, compared with 16s. 2d. in 1914; factories, 7s. 3d. per head, compared with 5s. 2d.; docks, 20s. 5d., compared with 25s. 3d.; mines, 29s. 6d., compared with 28s. 7d.; quarries, 17s. 4d., compared with 11s. 5d.; constructional work, 9s. 2d., compared with 14s. 11d.; and railways, 9s. 5d., compared with 8s. 4d.

In 1920, however, the average annual charge per head for compensation in these combined groups had risen to 14s. 4d., and the charge per workman in each individual group averaged as follows: in shipping 16s. 6d.; in factories 9s. 3d.; in docks 29s. 5d.; in mines 37s. 3d.; in quarries 19s.; in constructional work 13s. 5d.; and in railways 11s. 8d. There has thus been a substantial increase in the amount to be paid in 1920 compared with that of the preceding year. It cannot be argued that this increase is due to enhanced wages, since high, if not higher, wages obtained in 1919 than in 1920. The oncost charge for compensation in the mining industry in 1919 worked out at 1-82d. per ton of coal raised, and in 1920 to 2-44d. per ton.

Leaving at this point consideration of compensation for all accidents, let me now draw attention to industrial diseases in particular.

To establish a claim for compensation for personal injury, a workman must show that the accident was either an "accident arising out of and in the course of the employment" or that it was one of the industrial diseases within the meaning of the Act and as scheduled. In the Compensation Act, 1906, six industrial diseases only were set down in the third schedule, but power was given to the Secretary of State for the Home Department to enlarge the list of such diseases as required from time to time. At present, the list embraces about five times

the original number. It includes such diseases as ankylostomiasis, anthrax, miners' nystagmus, compressed air illness, nickel carbonyl, lead, and other poisonings, cataract in glass-workers, writers' and telegraphists' cramp, beat knee, beat hand, and beat wrist, and certain forms of cancer and ulceration due to various dusts and liquids.

But in addition to the diseases named under the third schedule of the Act of 1906, another disease—fibroid phthisis or silicosis—has been dealt with by the Legislature in the special Act, the Workmen's Compensation (Silicosis) Act, 1918. This disease in workmen, however, is differently administered from those diseases under the Compensation Act, 1906.

Schemes have been made for the refractory industries—mining and quarrying ganister rock and manufacture of ganister or silica bricks—whereby a general compensation fund, contributed to and administered by a Mutual Association of Employers in these industries, takes over the personal rights and responsibility of contributing employers, pools its finances, and dispenses compensation to disabled workmen rightfully entitled from the said general fund. The scheme also provides for a system of periodic medical examination of workmen employed in silica works, in order to prevent the development of the disease and, if required, to suspend from the employment any workman evidencing symptoms of commencing attack. It establishes also for each district a local joint committee of employers and workmen with an independent chairman, along with an expert Medical Advisory Committee, of which I am a member in the scheme for Scotland, to deal with cases of the disease. Too little time, however, has yet elapsed to permit of any definite opinion being formed regarding the prevalence of silicosis amongst those employed in these industries, and the operative value of the schemes.

The principle on which the Home Secretary has hitherto proceeded in determining the scheduling of an industrial disease is this: "That the disease or injury must be so specific to the employment that its causation by the employment can be established in individual cases." This seems a sound, safe, and direct principle, since it operates advantageously in instances in which a claim is made for the inclusion of an illness or disability which, although admittedly an illness or cause of disablement connected with a given employment, is not exclusively connected therewith—as, for example, bronchitis in

flax-workers, since bronchitis may originate from other causes than flax-working and in diverse ways.

It may now be asked to what extent do industrial diseases prevail, and what compensation falls to be paid for those disabled therefrom.

Tables III and IV state shortly these points for the years 1919 and 1920 respectively. Tables V and VI illustrate (1) the different Scheduled Industrial Diseases, (2) their Incidence in Occupations, and (3) the Total Cases in 1919 and 1920.

The foregoing Tables III and IV show that in 1919 the number of fatal cases from industrial diseases was 24, for which £4,722 were paid in compensation to dependants; and the number of disablements 10,074, for which £242,292 was paid; and for both classes of cases a total sum of £247,014 had to be paid. For 1920 the fatal cases numbered 27 and the disablement cases 10,425, for which the sums of £5,387 and £365,684 respectively were paid, making a total for that year of £371,671.

In 1919 the bulk of cases of industrial disablement occurred in the mining industry, chiefly due to nystagmus, beat hand, and beat knee. These numbered 9,175, or 90.9 per cent. of the total, nystagmus alone accounting for 6,449 of the 9,175. Dermatitis due to dust or liquids was responsible for 270 cases, or 2.7 per cent., and lead poisoning for 231 cases, or 2.3 per cent.

In 1920 the same was true of the mining industry, since 9,408 cases, or 90 per cent. of the total, was due chiefly to nystagmus and the other diseases named. From nystagmus alone there were 7,028 cases, being a marked increase in number from the previous year. Of the remainder, dermatitis showed 408 cases, or 3.9 per cent., and lead poisoning 265 cases, or 2.5 per cent. The 27 fatal cases included 18 from lead poisoning, 3 from anthrax, and one each from phosphorus, benzene, nitrous fumes, chrome ulceration, serotal epithelioma, and nystagmus.

With regard to the increasing number of cases of nystagmus, the Departmental Committee of 1920 suggested for the consideration of the Home Office that some special inquiry into this subject was desirable.

As has already been indicated, a Departmental Committee was appointed in 1919, the reference to which was as follows:

"To inquire into the working of the present system of the payment of compensation to workmen for injuries sustained in the course of employment, and to consider and report whether it would be desirable

* Annual Statistical Returns for 1920. Cmd. 1545.

to establish a system of accident insurance under the control or supervision of the State, and to report further, what alterations of the law will be required to remedy defects which experience has disclosed or to give effect to their recommendations."

The committee, after hearing evidence and procuring information from other sources, reported in 1920 (Report, 1920, Cmd. 816).

Several of the points dealt with in this report deserve some attention. The committee stated that the system of compensation, based upon the Workmen's Compensation Act, 1906, was of so comprehensive a character that it was a matter of immediate concern to the majority of the community, since it imposed a burden of upwards of £8,000,000 a year, and that its cost was an item which every business enterprise must take into account, as about fifteen millions of workers were reckoned to be within the scope of the Act.

It is more than likely that some of the recommendations of

this committee will constitute amendments to the present Act, and therefore a consideration of some of these may with profit be reviewed.

One of the subjects of immediate interest to all interested in compensation work had relation to the question: Whether any modification of procedure under the existing Act was necessary or desirable. The conclusion arrived at, after reviewing the present procedure and suggestions for amendment thereof, was that there was no need for any radical revision of procedure. It was pointed out that at present the certifying surgeon was not empowered to give a certificate of disablement after the workman had recovered from his disablement, and that hardship was not infrequently experienced by a disabled workman merely because of his ignorance of the procedure which he ought to pursue. To meet this, the committee suggested that it should be made compulsory for an employer to exhibit in conspicuous

places in his works notices directing the attention of the workman to the application of the Act to the scheduled diseases and the special steps to be taken by him for the purpose of claiming compensation, said notice also to contain information of the necessity for notice of any accident, trivial or otherwise, to be given to a designated person in the works, and adding that an accident book should be kept in which an entry shall be made of all ascertained accidents.

Witnesses drew attention to difficulties arising out of the issue by the certifying surgeon of a certificate in irregular form, and that in consequence substantial hardship to the workman followed. The committee recommended, first, that appeals to the medical referee on the ground of technical irregularity or flaw in the form of the certificate should not be permitted, and that it should be the duty of the registrar under the Act to scrutinize carefully every application for an appeal, and if he finds the certificate irregular in form, to return it to the certifying surgeon for amendment and notify the parties; and, second, that in any case where a certificate has been given in an irregular form, it should be open to the certifying surgeon at any time to issue a corrected certificate. Our experience is, that such amended procedure would be advantageous, as in not a few instances in which irregularity in form or flaw of certificate constituted the sole ground for allowing the appeal; there was thus delay in payment of compensation to the workman concerned.

According to the form at present prescribed (Form 15) for the decision of the medical referee on an appeal, a medical referee is not required to do more than state after inquiry whether he dismisses or allows the appeal; and when he allows an appeal against a refusal of a certificate of disablement by a certifying surgeon to a workman, to fix the date of commencement of the disablement.

The committee pointed out that an appeal may involve two or three distinct questions—namely, (1) whether the workman is or is not suffering from the scheduled disease; (2) whether or not he is disabled by it; (3) whether the date of disablement, if any, fixed by the certifying surgeon is correct. The committee concluded that the medical referee should be required to give his decision on each separate point referred to him, and they suggested that an opportunity should be taken to revise the form accordingly. It appears to me that the foregoing suggestions of the committee are likely to meet with the concurrence and approval of most medical referees who have encountered the points involved, but who have found themselves powerless to deal with them in Form 15 as at present framed.

This leads to other considerations affecting medical referees which came within the purview of the committee. The number of referees in England in 1919 was 238, in Scotland 81, and in Ireland 45. Seventy-five cases were referred to them for report by judges, arbitrators, and committees; 404 cases by parties' agreement for certificates; in 533 cases they sat with judges as assessors; in 282 cases they decided appeals against decisions of certifying or appointed surgeons in giving or refusing certificates of disablement on account of industrial diseases, and in 163 of these the certificates appealed against were confirmed.

In 1920 the number of referees for England was 206, for Scotland 80, and for Ireland 45. They sat as assessors in 414 cases (Schedule II, 5); 47 cases were referred to them for report by judges, etc., under Schedule II, 15; in 473 cases they were referred to by joint agreement of parties (Schedule I, 15); in 368 cases they decided appeals under Section 8 (1) (f), and in 205 of these the certificates appealed against were confirmed. Comparison of the figures for these years reveals a substantial increase in the numbers of references under Schedule I, 15, and Section 8 (1) (f), but a substantial decrease in the use of their services under Schedule II, 5 and 15.

The duty of a medical referee to make a report regarding a disabled workman on "any matter which seems material to any question arising in the arbitration" under Schedule II, 15, dates back to the Act of 1897, while that of giving a certificate in cases referred to him through the registrar on the joint application of parties (Schedule I, 15) and that of sitting as an assessor with a judge (Schedule II, 5) were enacted for the first time in the Act of 1906, and were based on the report of the Departmental Committee on the Act of 1900.

The committee of 1919 deem it of great importance that the fullest use should be made of the services of the medical referee

in any dispute relating to the cause and extent of the workman's incapacity. They were of opinion that it was advisable to extend Schedule I, 15, so as to provide that on an application being made the application may be made by either party in the dispute and on payment of the prescribed fee, and that in such case the registrar may, after hearing the parties and subject to a right of appeal from his decision to the judge, refer the matter to a medical referee. Respecting the employment of referees as assessors, the committee recommended that it should be open to either party, on giving security for the payment of the fee due to the referee, to obtain as of right a summons to the referee to sit as assessor, and further, that the referee should be given the right of asking through the judge questions of the witnesses, and of making, where necessary, a more thorough examination of the workman than is possible in court or in the judge's room.

State System of Insurance.

Having fully considered the question of the advisability or otherwise of instituting in this country a State System of Accident Insurance, the committee concluded that they "do not recommend the establishment of a State System of Accident Insurance," but they recommended that "every employer—other than the Crown, a local or other public authority, a statutory company, or a householder in respect of servants not employed by him for the purpose of his trade or business—shall be required to insure with an insurance company or in a mutual association against workmen's compensation risk, unless excepted as hereunder provided."

The exceptions being employers whose annual wage roll averages more than £20,000 over a period of three years, and who file an application to that effect accompanied by a declaration to the above effect and a certified copy of their balance sheet for the last trading year. The committee recommended that a substantial penalty should be provided for default so as to enforce compulsory insurance.

Not a little evidence was put before the committee regarding the necessary conditions which must be proved by a workman to ensure compensation for accident, the first being that he has sustained personal injury from an accident, and the second that it was an accident "arising out of and in the course of the employment." Suggestions were made by several witnesses, including county court judges, that the form of expression "arising out of and in the course of the employment" should be deleted from the Act, and that there should be substituted the expression "in the course of the employment," since in their opinion this latter expression would cover every occasion in which the relationship of master and servant would arise. While the committee agreed that "it is safe to say that no other form of words has ever given rise to such a body of litigation," they would not recommend any alteration in the existing form of words, observing that it was not without significance that other States in recent years, adopting legislation for workmen's compensation, have imported into their Acts the British form of words in the existing Act. They cite the fact that in all but four of the States comprising the United States of America the law reads that the accident must arise out of or result from the employment, and in all of these States, including the four indicated, the accident must happen in the course of the employment. The committee, therefore, recommended that the words of the present Act—"arising out of and in the course of the employment"—should remain unaltered.

The only other subject dealt with in the report of this committee which I shall consider is that relating to medical and surgical aid. The committee were much impressed with the evidence of numerous representatives of employers, trade unions, and insurance companies, as to the need for a comprehensive system of medical and surgical services for the rehabilitation of an injured workman and the restoration of his earning capacity. It was put in evidence that in some of the United States of America extensive provision of this kind exists, but that in this country nothing beyond the restricted scope of medical benefit under the National Health Insurance Acts was in operation. These Acts cover about fifteen million insured persons. Apart from Ireland—where no medical benefit is provided and where about 700,000 persons are insured under these Acts—what all these persons are entitled to, according to the Medical Benefit Regulations, to receive is—

"the treatment which a practitioner is required to give to his patients and comprises such treatment as is of a kind which can

consistently with the best interests of the patient be properly undertaken by a general practitioner of ordinary competence and skill."

This, however, as was pointed out, does not cover the needs of injured workmen, and further special services are required, such as massage, x-ray treatment, hydrotherapeutic treatment, in-patient hospital treatment, use of convalescent homes, and other forms. While the committee had no doubt of the great value of these in expediting the recovery of disabled workmen and their earning capacity, they did not think that the burden of providing these could be placed either on the shoulders of

the workmen or of the employers, but were of opinion that the solution of the matter lay in the direction of an extension of the services under the National Health Insurance Acts. As they understood that the Ministry of Health had under consideration a further development of medical services for the insured population generally, they would recommend that the extra services for injured workmen under the Compensation Acts should come under such a scheme and be co-ordinated therewith. They did not, therefore, feel justified or able to formulate a scheme. This, it will be obvious, opens up a very large question, and we must await what the future will bring.

The Stewart Prize.

AWARD TO DR. J. C. McVAIL.

THE Stewart Prize of the British Medical Association was presented to Dr. J. C. McVail at the General Meeting of the British Medical Association in Glasgow on the evening of Tuesday, July 25th.

The prize was founded by the late Dr. Alexander Patrick Stewart, who graduated M.D. Glasgow in 1838, and afterwards became physician to the Middlesex Hospital; he was among the earliest to give attention to sanitary questions and among the first to distinguish between typhus and typhoid fever. The primary object of the Stewart Prize is to afford recognition of important work already done or of researches instituted and promising good results regarding the origin, spread, and prevention of epidemic diseases.

The prize has been awarded to Dr. McVail in recognition of the important work he has done during a long life devoted to public health. He began his professional career in 1873. He was first of all in general practice and his association with public health dates from the time when he began to assist the medical officer of health for Kilmarnock, whom he ultimately succeeded. He became the first medical officer of health for the counties of Stirling and Dumbarton in 1891, a position he held for over twenty years. His painstaking investigations, his lucid reports, and his wisdom in counsel displayed during the period of his appointment placed him in the front rank of public health officers. His reputation as a far-sighted and impartial investigator was so well established that when, in 1907, the Royal Commission on the Poor Laws and Relief of Distress desired to have special inquiries made into the methods of administering indoor and outdoor relief, Dr. McVail was chosen to make those inquiries, and his report to the Commission is a fascinating record of patient industry and clear thinking.

Dr. McVail's attention was first turned to vaccination by the study of statistics of Kilmarnock for the years 1723 to 1764. The records of death afforded appalling evidence of

the great prevalence of small-pox among children in the eighteenth century. He was thus led to make an extensive study of vaccination; he embodied the results in a book entitled *Vaccination Vindicated*, the first edition of which appeared in 1839; it at once became the chief authority on the subject. His knowledge of the subject was so extensive that his evidence before the Royal Commission on Vaccination occupied no fewer than twelve days. In 1919 he brought up to date our knowledge of the subject in the Milroy lectures delivered before the Royal College of Physicians of London.

When the National Insurance Act of 1911 came into force Dr. McVail was appointed Deputy Chairman of the Scottish National Insurance Commission, a position he held with great advantage to the community generally until, on the abolition of the Commission and the creation of the Scottish Board of Health, he became the medical officer concerned with health insurance; he has just retired from the service. While Deputy Chairman of the Scottish Insurance Commission he was a member of the committee appointed by the Commission which inquired into the medical services in the Highlands and Islands, and he was also a member of the Astor Committee on Tuberculosis.

"THE BOOK OF GLASGOW."

EVERY member attending the Annual Meeting of the British Medical Association in Glasgow this week has received a copy of the *Book of Glasgow*,¹ whose appearance was briefly noted in our last issue. This handsome volume of 258 well-printed pages, with more than 50 illustrations on art paper, forms an agreeable introduction to the city and its institutions, and will be prized as a souvenir. Its object is to give the visitor a series of impressions of Glasgow from various points of view, and the Printing and Publishing Committee must be congratulated both upon their choice of authors and upon the excellence of the production. The material is arranged in nineteen sections, and each writer has followed the method best suited to his own outlook and style of composition, so that the general effect is one of pleasant variety. Thus the volume, as the chairman of the committee (Dr. William Snodgrass) insists in his preface, is not to be regarded in any sense as a guidebook but as a collection of articles on the most interesting features of Glasgow and its history, written by a group of distinguished journalists and literary authorities, with the general editorial assistance of Mr. R. T. MacLennan of the staff of the *Glasgow Herald*.

The first chapter, from the pen of Professor Glaister, gives an interesting historical sketch of the University from its foundation in 1451 down to the present time, with special attention to the development and progress of its medical school, and to the library and Hunterian collection. Dr. Oliphant describes the Royal Faculty of Physicians and Surgeons and its founder, Peter Lowe, who obtained a charter

from the King in 1599. Dr. John Fergus gives a comprehensive account of the medical institutions of Glasgow, in somewhat fuller detail than his recent article in our columns. Readers of the JOURNAL will recognize also Dr. John Patrick's interesting article on the Glasgow School of Medicine, Mr. William Power's sketch of Glasgow to-day, and the poem on the arms of the city of Glasgow written by Dr. Robert Mayne, first professor of physic in the University from 1637 to 1641. Other verses comprise the "Kirkyard Eclogue" in honour of the old Royal Infirmary, written in the Doric by the late William Findlay, M.D. ("George Umber"), and the ingenious and well-turned lines by Dr. John Fergus, entitled "Maister Peter Redivivus," wherein the shade of Peter Lowe is supposed to be paying a visit to the Faculty:

"Imagine Peter, as I say,
Meeting our President to-day."

The remaining articles, with the exception of Mr. W. Stewart's remarks on Glasgow medical men and literature give impressions of the city from standpoints other than the medical. They include brief historical notes on ecclesiastical Glasgow in pre-Reformation times, by John Edwards, LL.D. on Glasgow of old, by George Eyre-Todd, and on the traditions of the trade houses, by Harry Lumsden; a sketch of the Clyde, its shipping and its docks and shipyards, by Neil Munro; descriptions of business life in Glasgow and its municipal services, by G. B. Primrose and James Willock; notes on Glasgow artists and the works of art preserved there, by T. C. F. Brodie and R. T. MacLennan; a study in contrasts entitled "Glasgow a frontier fort," by George Blako; and, lastly, an outline of the history of golf in this neighbourhood and of the courses open to members during the Annual Meeting.

¹ *The Book of Glasgow*. Prepared under the direction of the Printing and Publishing Committee for the Ninetieth Annual Meeting of the British Medical Association, July, 1922. Glasgow: Alex. Macdonnell. 11p. 25s. with 53 plates. Price 5s.

The Gold Medal of the British Medical Association.

THE Gold Medal for Distinguished Merit of the British Medical Association was presented to the Right Hon. Sir T. Clifford Allbutt and to Lieutenant-Colonel Arthur Martin-Leake, V.C., F.R.C.S., at the general meeting of the British Medical Association in Glasgow on the evening of July 25th, 1922. The presentations were made by the President, Sir William Macewon, F.R.S., on behalf of the Association. The medal for distinguished merit was instituted by the British Medical Association at its annual meeting in Manchester in 1877. The medal is awarded on the recommendation of the Council to some person who shall have conspicuously raised the character of the medical profession by scientific work, by extraordinary professional services, or by special services rendered to the British Medical Association. On this occasion the medal was in each case accompanied by a testimonial or address stating the grounds of the award, and this practice will be followed in future.

BRITISH MEDICAL ASSOCIATION MEDAL FOR DISTINGUISHED MERIT.

SIR CLIFFORD ALLBUTT.

The following is the text of the address presented to Sir Clifford Allbutt:

To the Right Honourable

SIR CLIFFORD ALLBUTT, K.C.B., M.D., LL.D.,
F.R.S., Regius Professor of Physic in the University of Cambridge, President of the British Medical Association, 1916-1921.

We delight to honour in you a great physician, a great teacher, and a wise friend in counsel. From the time when, as a young man, you joined the staff of the Leeds Medical School, the high reputation of which you were destined to enhance, you have never ceased to uphold the traditions of British Medicine, among whose leaders your name will always be numbered.

We recall how fifty years ago your book on the *Ophthalmoscope in Medicine* not only taught the profession the value of a new means of investigating disease, but revealed a new clinical observer whose future work, should his life be spared, could not fail greatly to benefit the science and practice of medicine. To these early days, too, belong your epoch-making investigations into the cause of certain forms of disease of the brain and spinal cord and into the effects of strain on the heart and great vessels. It was at this stage also of your career that you invented the short clinical thermometer, which at once superseded the clumsy instrument some of us can remember holding precariously in the mouths of reluctant patients; it was a mechanical improvement indeed, but one that greatly helped us in our daily work, and one the need for which could only have occurred to a physician actively engaged in clinical practice.

A little later the outspoken criticism contained in your Goulstonian lectures on visceral neuroses had a wholesome influence in moderating the extravagances of a passing phase of medical practice.

We recall also how in two addresses to the British Medical Association you unfolded ideas which have occupied a large place in your mind. In your address as President of the Section of Medicine in 1882 and again in the Address in Medicine, delivered in the hall of this ancient University, when the Association, in 1888, last

held its Annual Meeting in Glasgow, you pleaded for a broader outlook, and demanded that our inquiries into the nature and causes of disease should not be limited to man, nor even to the animal kingdom, but should be extended to plants which present, in a simpler form, problems not dissimilar. That the dominant principle of this message, the need for unity in the study of disease in its widest aspects, had always remained with you is made clear by a passage in your Presidential Address at the opening of the Annual Meeting at Cambridge in 1920: Though you had then still to speak rather of your hopes than of their realization, you were able to point to some encouraging signs that the importance of the matter was beginning to be understood.

The expectations built on the originality and wide grasp of essential principles displayed during this early period have been more than justified. You have been granted long life, and every day of it has been full of labour, as congenial as it has been fruitful, to advance the science of medicine, full of service for the profession to which you have unsparingly given sympathy and help, and full, also, perhaps the greatest of your merits, of inspiration for others. Nor did you unwisely neglect due rest and recreation, finding them, after your energetic fashion, in the arduous sport of mountaineering.

After you settled in Leeds, your name as a helper in time of need quickly became known to your brethren alike in the great towns and in the northern valleys of Yorkshire. It was therefore with no little regret that the profession heard in 1889 of your acceptance of the position of Commissioner in Lunacy. Looking back we may, perhaps, perceive that this episode was needed to complete your experience of medicine in all its aspects. Everything that had gone before was, we may now see, but a preparation for the great office to which you were called in 1892.

You returned to Cambridge, your old University, at a time of transition, when the possibilities of science, not merely for its technical achievements, but as a mental discipline, were being forced by Humphry and

Photograph (by Mr. W. G. Parker) of the frontispiece of the Address presented to Sir Clifford Allbutt with the Gold Medal of the Association. The dominant colours in the original are red and blue, enhanced by gold. It has been designed and painted by Mr. Frederic G. Hallett.

Michael Foster on the attention of those who stood in the ancient ways, and when a call to return to the study of nature was finding an echo in halls where for generations it had hardly been heard. We do not doubt that your own attainments as a scholar and historian, attributes the fruit of which are to be found in many addresses and have in those later days so ominously been displayed in your monumental work on *Greek Medicine in Rome*, contributed not a little to the achievement of the task you undertook. How great that task was, and in how large measure its accomplishment was due to your strength of purpose, and gentleness in method, to that combination of sweetness and light praised by Matthew Arnold, we will not stay to consider. It has already become part of the history of the University, and the chapter we rejoice to think is not closed.

But you have not allowed your exacting duties as Regius Professor of Physic to deter you from continuing to add to the store of medical knowledge, nor from taking an active share in its dissemination. The *System* with which you first endowed the profession in 1896, though the work of many minds, reflected everywhere the qualities of your own, and displayed an anxiety, while taking advantage of the latest results of laboratory work, always to maintain the supremacy of clinical methods in the practice of our art. The conception of hyperpnoea finally presented in your book on *Diseases of the Arteries and Angina Pectoris*, a work of your later years, would alone have sufficed to establish the reputation of a lesser man.

We, members of the British Medical Association, are proud and grateful that you were our President through the troubled years of war, and that after the great meeting of the Association in Cambridge in 1920 the Crown added to its earlier appreciation the further honour of calling to the Privy Council the youthful Nestor of our profession.

In token of our respect and affection for you as a man, of our admiration for you as a physician and teacher, and of our gratitude to you for the generous spirit in which you gave freely of your time and wisdom to the Association during a period of unexampled strain and difficulty, we ask you to accept at the hands of our President the British Medical Association's Gold Medal for Distinguished Merit.

July, 1922.

ARTHUR MARTIN-LEAKE, V.C. (WITH BAR), F.R.C.S.

The following is the text of the address presented to Lieutenant-Colonel Arthur Martin-Leake:

To ARTHUR MARTIN-LEAKE, V.C. (with Bar),
F.R.C.S.

The British Medical Association in 1877 instituted a Medal "for Distinguished Merit" to be awarded under such conditions as the Council of the Association might determine. One of the conditions of the award was that the Medal should be given to any person "who shall have conspicuously raised the character of the medical profession by scientific work, by extraordinary professional services, or by special services rendered to the British Medical Association."

Members of the Association noted with great satisfaction that in 1902 His Majesty King Edward VII awarded to you the Victoria Cross under the following circumstances:

"For great devotion to duty and self-sacrifice at Viakfontein, February 8th, 1902, when he went out into the firing line to dress a wounded man under very heavy fire from about forty Boers only 100 yards off. When he had done all he could for him he went over to a badly wounded officer, and while trying to place him in a more comfortable position he was shot three times. He only gave up when thoroughly exhausted, and then he refused water until other wounded men had been served."

The Address is illuminated and written in a bound volume of fifteen pages, including title-page. It is a very beautiful work of art, for the production of which the British Medical Association is greatly indebted to the artistic skill of Mr. Frederic G. Hallett. It has been to him, we know, a labour of love. The result is a production worthy of the occasion and one which, we feel confident, will prove grateful to Sir Clifford Allbutt as some memorial, with the medal, of his long connexion with the Association and of the great services he rendered to it while its President during so many years of the war.

Mr. Hallett has designed and illuminated the title-page, decorated panels, and tail-pieces; and the text of the address has been written in gold, colour, and black, by Miss Melinda M. Baker. The title-page, which is richly illuminated, contains in the upper border the arms and crest of the Regius Professor of Medicine, in the left border the arms of Cambridge University, in the right border the arms of Gonville and Caius College, and in the lower border a water-colour painting of the building of the British Medical Association. Page 1 has a decorated panel enclosing a water-colour painting of a corner of Park Square, Leeds, where Sir Clifford Allbutt practised when physician to the Leeds Infirmary; in the distance is a view of the Leeds Town Hall. The initial letter of this page encloses a water-colour painting of Lake Windermere. Pages 3, 5, 7, 9, and 11 have decorated panels enclosing water-colour paintings. On page 3 there is a painting of the front view of Caius College, Cambridge, with the Senate House. On page 5 is a water-colour sketch of the Gate of Honour, Caius College, at sunset. Sir Clifford Allbutt was an undergraduate of Caius College and is now a Fellow. On page 7 the panel contains a water-colour painting of the Eiger, Mönch, and Jungfrau Mountains—a reference to Sir Clifford Allbutt's achievements as a mountaineer. On page 9 there is in the panel a water-colour painting of Tree Court, Caius College, and on page 11 a water-colour drawing of the "Backs" at Cambridge, showing Clare College Bridge over the Granta. On page 12 there is a tail-piece, including the monogram of the British Medical Association, and on page 14 a decorated panel, enclosing the signatures of the officers of the Association. The volume is bound in rich brown morocco leather and hand-tooled in gold by Messrs. C. and C. McLeish, and the ornamentation on the front cover, which includes the monograms of Sir T. Clifford Allbutt and the British Medical Association, is from the design of Mr. Hallett.

In February, 1915, the following notice appeared in the *London Gazette*:

"Bar to Victoria Cross. For most conspicuous bravery and devotion to duty throughout the campaign, especially during the period October 29th to November 8th, 1914, near Zonnebeke, in rescuing, whilst exposed to constant fire, a large number of the wounded who were lying close to the enemy's trenches."

You were the first medical man and the first of His Majesty's subjects to be awarded a Bar to the Victoria Cross. This is a distinction of which not only yourself but the profession and the Association of which you are a member have every reason to be proud. On behalf of the Council of the British Medical Association we ask you to accept at the hands of our President the Association's Gold Medal for Distinguished Merit.

July, 1922.

The Address, suitably illuminated and engrossed, is contained in a volume bound in blue morocco, bearing in gold on the cover the symbol of the staff and entwined serpent and the monogram of the British Medical Association. The Address, as is that to Sir Clifford Allbutt, is signed by Professor Drummond, President, 1921-22; Sir William MacEwen, President; Dr. Wallace Henry, Chairman of Representative Meetings; Dr. R. A. Bolam, Chairman of Council; and Dr. W. E. Haslip, Treasurer of the Association.

THE BRITISH PHARMACEUTICAL CONFERENCE.

PRESIDENT'S ADDRESS.

THE annual British Pharmaceutical Conference was opened at University College, Nottingham, on July 26th, when the President, Professor H. G. GREENISH, D.Sc.Paris, delivered an opening address on pharmacognosy and the pharmaceutical curriculum. The subject is especially his own by reason of his position as Professor of Pharmaceutics in the School of Pharmacy of the Pharmaceutical Society.

Pharmacognosy, he said, is a pursuit for which the pharmacist is particularly fitted by the nature of his vocation and the opportunities afforded him of becoming expert. The unique museums, herbaria, and library of the Pharmaceutical Society and its fine record of eighty years' work entitles it to be regarded as the headquarters of pharmacognosy in this country.

Definition of Pharmacognosy.

Explaining what pharmacognosy actually comprises, the President showed that its description as "to know what the drug is, what it costs, and how long it will keep," is inadequate. A proper knowledge of it required the study of botany, chemistry, physics, and zoology as well as a good acquaintance with geography, history, ethnology, and etymology. The practical application of pharmacognosy was the work of the pharmacist, who in learning the practice of his vocation should realize that the higher responsibility of those who provide the public with medicines calls for a complete understanding of the origin, mode of preparation, and constitution of his materials:

Preliminary Education.

He drew attention to the necessity of a good preliminary education, and deplored the decision taken by the Pharmaceutical Society in 1897 in reference to the entrance examination; the effect of an inferior standard in preliminary education during the last twenty years had been painfully evident to his own observation. The effort of teachers during this period to erect a solid edifice on insufficient foundation had in many cases proved to be an impossible task. The Royal Commission on University Education in London had reported to the same effect, and had pointed out that in the absence of a sound general education a large part of the benefits of university training are lost.

Scientific Training.

He next dealt with the arrangement of the scientific training to be followed. He placed botany foremost on account of its important relation to drugs. Should this knowledge, he asked, be acquired previously to pupillage in pharmacy or afterwards? Opinions varied: in Belgium the scientific training precedes the entrance to practice of pharmacy, in France the accessory sciences were taken up later; but in both cases the scientific training was continuous. In England the entrant into pharmacy was debarred from adopting the Belgian plan in its entirety, and had usually followed the French plan simply. Under the present (new) regulations he might adopt an intermediate course, but this would involve a two years' interruption in the continuity of his studies, and such interruption had been observed invariably to produce bad effects. The experience of those who had to interrupt their studies on account of the war afforded a notorious example.

Turning to the method of training in botany, he pointed out the need for a specialized course of instruction adapted to the particular objects in view. The Minister of Education in Austria had some years ago expressed the same view.

The President next described in some detail the scheme of training proper for students of pharmacognosy, emphasizing the importance of instruction in the use of the microscope. Referring to the syllabus of examination for pharmacists, he quoted from the report of the Royal Commission the statement:

"The syllabus is a device to maintain a standard among institutions which are not all of university rank. The effect upon the students and the teachers is disastrous. . . . They cannot pursue knowledge both for its own sake and also for the sake of passing the test of an examination. And the teachers' powers are restricted to the syllabus; their freedom in dealing with their subject in their own way is limited."

The syllabus, if such there must be, should be couched in terms as general as possible. Both teachers and examiners should be pharmacists, either men or women, who had received a thorough training in pharmacognosy.

Advanced and Post-graduate Training in Pharmacognosy.

For advanced training in pharmacognosy, or that by which men become leading authorities on sections of the subject, he commended to all students higher ideals than those merely sufficient to qualify them for the practice of their vocation. In this connexion the need of post-graduate work and opportunities for carrying out research should be recognized. It would not be too much to say that the training in pharmacognosy was incomplete until research had been undertaken and accomplished. There was now an incentive to students to continue in this aim, for by means of work accomplished in the Pharmaceutical Society's Research Laboratories they could proceed to the degree of Doctor of Philosophy. It was desirable that pharmacognosy should be accepted by universities as one of the subjects for the degree of Bachelor of Science, as had been done by the Universities of Manchester and Glasgow.

The field of pharmacognosy was wide, and the problems awaiting solution were diversified. They required men of varied qualifications and abilities such as Bourquelot, Power, Henry, Perrot, Farr, Wright, Goris, and that unrivalled master of botanical identification, E. M. Holmes. He deplored the lack in this country of an experimental station for pharmacognosy such as that at Wisconsin for the cultivation and study of drugs; that was a co-operative enterprise between the department of pharmacy of the university and a department of the Bureau of Plant Industry of the United States. It received 5,000 dollars a year from the Federal Government, and was aided by pharmaceutical firms interested in the work. At present the Pharmaceutical Society's Research Laboratories had no place where the material necessary for their work could be grown; they depended for assistance—always most willingly given—on the Director of Kew Gardens and the Curator of the Chelsea Physic Garden.

One of the most important of the subjects awaiting investigation was that of the part played by alkaloids in the metabolism of the plant. Until light was thrown on this question no rational scheme was possible for obtaining larger proportions of alkaloids from plants. The advantages for the prosecution of this work enjoyed by this country, with the variety of her colonial possessions, were recognized long ago, and were pointed out by Dr. Jonathan Pereira when appealing for the appointment of a scientific committee for the promotion of pharmacological knowledge.

University Degrees for Pharmacists.

Professor Greenish went on to describe the conditions under which degrees in pharmaceutics were granted by the Universities of Manchester and Glasgow. A proposal had been made for the establishment of a College of Pharmacy which should be recognized by the University of London. The President further reminded his hearers of the objects of the great men who were the founders of the Pharmaceutical Society, and alluded to the fact that the chemical laboratory established by them for the teaching of chemistry was the first in this country. At that time the Committee for Promotion of Pharmacological Knowledge consisted of fourteen members of the Society's Council, with fourteen honorary members and others, among whom no fewer than eleven were Fellows of the Royal Society; this showed the high recognition then paid to their body. For many years the Council of the Pharmaceutical Society had continued its endeavours to raise the Society to the rank of a learned body, and so to acquire the influence that it ought to possess, but recently that policy had receded into the background. At this moment, however, he felt hopeful of a revival of the former spirit; he could distinguish evidence of a determination to foster scientific work, and he expressed the hope that the Society, mindful of its great traditions, should set its educational policy steadfastly in the direction indicated by the wisdom of its founders, should foster the love of the calling which distinguished those early years, and so ensure for itself due appreciation.

A CONFERENCE of representatives of metropolitan county councils was held at the Islington Town Hall last week to consider the need for the amendment of the law relating to the sale of unsound food, so as to empower sanitary authorities to prosecute the wholesaler as well as the retailer. The conference adopted a resolution calling the attention of the Minister of Health to the necessity for the law relating to the sale of unsound food being amended by the addition of the following words at the end of section 47 (3) of the Public Health (London) Act, 1891, "and had taken reasonable steps to ascertain that the article was not in such a condition as to be liable to be seized and condemned under this section." It was further resolved to ask the Minister to receive a deputation on the matter.

British Medical Journal.

SATURDAY, JULY 29TH, 1922.

BRAIN SURGERY.

THE Presidential Address delivered to the British Medical Association by Sir William Macewen on Tuesday evening is published in full in this issue. Its main topic was the history and present position of brain surgery, and it will be read with interest by all—surgeons, physicians, and general practitioners alike—not only in Great Britain, but throughout the world. It is from the mouth of one of the pioneers, from one who all his life has laboured to advance knowledge with consummate precision, integrity, and skill.

It will be somewhat astonishing to the younger generation to realize that almost all of our modern knowledge of cerebral function has been built up within the lifetime of one still happily amongst us. Sir William Macewen tells us that he was taught as a student that the brain acted as a whole, and that there was then no recognition of functional localization. He goes on briefly to sketch some of the outstanding advances which have been made. Chief amongst these is the recognition that different physiological functions dwell in different parts of the brain. This discovery is paramount, because it was through it that surgical removal of pathological products became possible. For the successful treatment of cerebral tumours three conditions must be fulfilled: first, that the presence of a tumour be recognized; second, that the situation of this tumour should be accurately forecasted; and third, that a technique should be employed which will allow of its removal. The recognition of the presence of a cerebral tumour is often not difficult, especially to those who are able to make an examination of the optic nerve-head.

There is a general impression that brain tumours are rare, and not often to be thought of. Rarity is a comparative term, but in the sense in which the word is employed in the designation of rare diseases, it is not applicable to cerebral tumours. It is true that these neoplasms are not extremely common, but they are not rare in the sense, for instance, that spinal cord tumours are rare. If we turn to the statistics of the more famous neurological surgeons we get the impression perhaps that intracranial tumours are even plentiful. Dandy, for example, in a recent paper states that within a given period more patients were admitted to the Johns Hopkins Hospital suffering from tumours of the brain than from tumours of any other organ. In this instance there is a special reason for abundance—namely, the practice of ventriculography which Dandy has introduced and (perhaps unfortunately) popularized.

We have thought it just to make these remarks on the frequency of cerebral tumours because there are practitioners who feel that the occurrence of a cerebral tumour in their own practice is an unlikely contingency. It arises partly out of this that, as a general rule, cerebral tumours come to the surgeon too late. There is a feeling abroad that a decompressive operation is about as much as can reasonably be done for such a case. This is almost the same as saying that a gastro-enterostomy is the most that can be effected for a pyloric carcinoma—palliation, not cure. We must aim higher than that. We must aim at the actual removal of the tumour, just as we should were the growth elsewhere in the body. This can be done with least risk when the tumour is small, and we are thus brought back to the importance of functional localization. As Sir William Macewen says, an exploratory operation on

the cranial chamber, after the manner of an exploratory coeliotomy, is not feasible. Within the abdomen it is possible to be upwards of twenty feet wrong in one's diagnosis—to believe the disease to be a duodenal ulcer and to find a diseased appendix—and, without detriment to the patient, to rectify matters through the one incision. Within the skull this happy state of affairs does not obtain. It is to a large extent the need for this nicety of knowledge which has attracted so many to what some of the more easy-going amongst us regard as an impossible allegiance. Sir William Macewen's name ranks amongst the highest of those who in these isles have worked to such purpose in this field. And this is no small thing to say, for the British school of brain surgery has always been in the very vanguard of the world, and we are justly proud of it. The work on pyogenic diseases of the brain and its membranes, published many years ago, remains to this day the classical monograph on the subject. And his remarks this week, out of his ripe experience, complete the tale. What he has to say of cerebral tubercle is of great interest, particularly with regard to the secondary infection of latent tuberculous foci.

In the realm of brain surgery much remains to do. We have not yet by any means reached the limits of possibility in localization of tumours of the so-called "silent areas," but little by little even those fastnesses are being reduced. Nor have we reached anything like perfection in our methods of dealing with brain tumours even when exposed at operation. Earlier diagnosis should help us to effect cures rather than achieve only some amelioration.

It has been our President's lot to have worked courageously, long, and untiringly, and he is indeed fortunate to see such fruition before eyes which in the early pioneering days must often have been baffled and dejected.

INDUSTRIAL DISEASES AND FORENSIC MEDICINE.

THE address by Professor Glaister, President of the Section of Industrial Diseases and Forensic Medicine of the Annual Meeting of the British Medical Association in Glasgow, published in full in this issue, touches on various matters of interest and importance, not merely to specialists, but to the whole practising profession of medicine. The scope of forensic medicine, as taught in the schools, has varied from time to time in accordance with the extending relations of medicine to the State, and it is clear that such changes are not at an end. Sometimes one subject within the course of lectures has come to bulk so largely as to make it desirable to establish a separate lectureship, especially in Public Health. At another time a teacher, looking to new demands, may have concluded that, as general practitioners are not likely to be called on, or to be qualified to make, a chemical analysis of the contents of a stomach in a case of suspected poisoning by an alkaloid, he might properly cut down the time devoted to toxicology. At present the doctor's responsibilities under the Acts relating to industrial diseases are becoming more and more onerous, and Professor Glaister has done wisely in directing special attention to the subject.

Before entering on it, however, he raised two general questions: one is whether all matters involving the application of the science of medicine to the law should not be included in the course of forensic medicine. While he reaches the conclusion that the time is not ripe, he admits that there is much to be said on both sides. It seems to us that here there need not be uniformity of method in all schools, but that every group of

teachers should agree between themselves as to the best system in the circumstances of their own institution. The essential is that the legal aspects of every part of his tuition should be made clear to the student. Whether the duty should be distributed, or be concentrated under one teacher, is a detail, though doubtless an important one, and, looking to pending demands on the student's time, overlapping should be most carefully avoided. The other general question is whether law students should not be required to pass an examination in forensic medicine as an essential part of their qualifying courses. Dr. Glaister urges that they should, and surely he is right. It appears that already in Scotland every candidate for the Bar must study and pass in forensic medicine. Law and medicine would then react beneficially on each other; a medical witness would be the better able to answer if counsel could in some measure meet him on his own ground. We have, indeed, heard it said of a famous teacher who conducted separate classes for law and medical students, that he had a very attractive way of dealing with his subject from the point of view, in the one class, of a doctor in the witness box, and in the other class, of a lawyer cross-examining the doctor. When two of his old pupils came against each other in a disputed case each would no doubt recognize, in thrust and parry, the influence of their common master, who was himself unsurpassed in skill of fence.

Professor Glaister's main subject was industrial diseases. He traced the history of compensation to workmen from the days when common law was the only resort, on through the successive Acts of 1880 (the Employers' Liability Act); the first Workmen's Compensation Act of 1897, which imposed liability quite independently of contributory negligence; the Act of 1900, which extended the law to cover agricultural employees; and the third Compensation Act, which has remained unaltered in terms, though not in administration, since it was passed in 1906. Though still excluding casual labourers and share fishermen, it embraces practically all other workers earning up to £250 a year under a contract of service. It also provides for the appointment of medical referees to sit with the tribunals in disputed cases as assessors, of whom, as it happens, Dr. Glaister is one, acting for the great industrial area of Glasgow and the West of Scotland. A table is quoted showing that the number of workmen under the Act was well over eight millions in 1920, and that the industrial diseases scheduled have increased about fivefold since 1906. In respect of silicosis a special Act was passed in 1918, and is notable for having applied to such workers the principle of periodical medical examination apart from existing illness, and solely for the purpose of disease prevention—a principle which, when suggested for general adoption, was rejected by the Royal Commission on the Poor Laws in its report in 1909, but is now in operation throughout the whole of school life.

An important Departmental Committee was appointed in 1919 to inquire into the present system of workmen's compensation, and to advise whether accident insurance should be adopted. Some of the findings of that Committee in its report of 1920 are discussed in Professor Glaister's address. He mentions without comment the Committee's reckoning that about fifteen millions of workers were within the scope of the Act. The table which he had already given states the figure for the same year (1920) as between eight and nine millions. Under the National Health Insurance Act fifteen millions must have been approximately correct for Great Britain even in the early years of that Act, whilst the wage limit of £250 a year, under the Compensation Act of 1906, together with its exclusion of casual labourers, would have led us to suppose the tabulated figure (8,348,150) to be correct, rather than the estimate of fifteen millions.

The Committee recommended that the wage limit should be raised from £250 to £350, looking to the general rise in wages, but that was in 1920, and since then there has been a fall. The total annual cost to employers in the seven industrial groups increased from £2,700,325 in 1910, to £4,616,723 in 1919, and further to £5,978,009 in 1920, whilst the total burden of the Act exceeded £8,000,000 a year.

It is not surprising that the Departmental Committee reported in 1920 that special inquiry should be made as to miners' nystagmus. In 1919 compensation was paid for 6,449 cases of that affection, and in 1920 for 7,028 cases. Apart from Professor Glaister's address we may call attention to the fact that in the present year a special committee of the Medical Research Council issued a very important first report on the subject. It concluded that the essential cause of the disease is deficient illumination owing to the low power of ordinary safety lamps, and to absorption of light by coal and by dust-covered surfaces. The disease is very prevalent, but only a small proportion of cases are so severe as to cause even temporary incapacity for underground work. The Committee recommended that the illuminating power of safety lamps be greatly increased, or that an electric light be fixed on the miner's head or belt, and that the walls of the workings apart from the coal face be white-washed. It expressed the belief that by such measures the disease as a cause of disablement might by degrees be entirely prevented. That is a most important deliverance.

As regards the Compensation Act in general, the Departmental Committee concluded, as pointed out by Professor Glaister, that there was no need for much revision of procedure, though employers should be compelled to give publicity within their works to the provisions of the Act, for the guidance of their workers in claiming compensation, and an accident book should be kept in every workshop. It considered also that the registrar should examine the factory surgeon's certificates in cases of appeal, and should return them to him for correction of any irregularities. This simple procedure, Dr. Glaister holds, would appreciably facilitate administration. The Committee further advised that every report by a medical referee should state specifically whether the workman was suffering from the scheduled disease, whether he was thereby disabled, and whether the certifying surgeon had correctly stated the date of disablement. Another recommendation was that additional facilities should be provided to render resort to the services of the referee easier. To meet the financial risks of smaller employers and of householders compulsory insurance is recommended. The Committee was favourably inclined towards extension of the scheme of the National Insurance Act to meet the needs of injured workmen, but this, as Dr. Glaister remarks, opens up a wide question.

The whole address is so packed with information which every practitioner ought to possess that the report of it in to-day's issue should be preserved for reference.

ECONOMY AND INFORMATION.

In our issue of June 24th we referred to the great increase in the price of Stationery Office publications, and pointed out the dangers, from the point of view of the medical profession, of the course upon which the Treasury had entered. We are very glad to see that Dr. Fremantle has taken up this matter in the House of Commons. On July 3rd he asked the Secretary to the Treasury to "state the reasons for the increase in price of the Annual Report of the Registrar-General for Scotland from 5s. to £2 17s. 6d.; if, in fixing the latter price, regard has been had to the restricted circulation that will result and the lessened use of the findings—

of the Registrar-General's Department by local authorities and by the public at large; whether it is proposed to increase similarly the cost of the annual report of the Registrar-General for England and Wales and other official publications; and whether, before fixing prices, he will consult the Ministers concerned in regard to the value of the publications to the public welfare." Sir John Baird promised to make inquiries and subsequently wrote to Dr. Fromantle in the following terms:

Dear Fremantle,

As promised in my reply to your question on 3rd instant I have looked into the pricing of the Scottish and also of the English Registrar-General's Reports.

The reason for the large increase in the price of this and other Government publications is that the Government has decided that in view of the present financial condition of the country it would no longer be justified in selling official publications at prices far below cost. In calculating this nothing is included for the cost of preparation, and all copies used for official purposes are treated as sold at the published price. It is not as if the low prices hitherto charged had led to wide circulation. You will no doubt be surprised to learn that the sales of the previous report of the Registrar-General for Scotland (priced at 5s.) only amounted to 74 copies, the majority of the purchasers no doubt being local authorities, in whose interests very largely the report is published.

I must say, however, that the price of 57s. 6d. seems to me too high, and as I find that it is still not too late to make a reduction I am having it altered to 30s., and I will have careful note made of the sales to enable me to judge whether it would be to the interests of the Exchequer to fix it still lower next year. I may say, however, that our experience hitherto with publications of this character is that their restricted circulation is not very responsive to variations in price.

The real question to my mind is whether we are justified, in view of the very small demand for this work, in publishing all the elaborate tabular matter in the report, and I am pursuing this aspect of the matter. The corresponding English report, which has a considerably larger sale, is being issued at 20s.

As regards the last part of your question I would add that we are frequently in consultation with Government departments as to the prices of their publications.

July 17th.

Yours sincerely,
JOHN BAIRD.

Sir John Baird's interesting letter shows that Dr. Fremantle has already secured a useful concession, and we hope that he will pursue the subject, for in our opinion the Secretary to the Treasury still does not fully realize the gravity of the issue. The price of the last report of the Registrar-General for England and Wales was 7s.; that of the report just issued is 20s., or nearly three times as much. It appears to us that the very small circulation of the Scottish Report at its old price, although not, we are afraid, very creditable to the Scottish public, is no argument for an increase, but proof that even the old price was too high. The intellectual level of discussion of public health problems must continue to be low so long as the general public are ill informed respecting the essential facts; they cannot be well informed unless they are familiar with the principal contents of the reports of the Registrars-General of Great Britain. Sir John Baird's expedient for meeting the difficulty by reducing the bulk of the reports is, we think, a dangerous one. There is perhaps a case in favour of issuing a new document summarizing the most essential facts and to be sold at a very low price, but this should be in addition to the present reports; the latter ought to continue to be within the purchasing power of both the new and the old poor. We are extremely suspicious of inquiries pursued by Treasury officials and other laymen into the value of "elaborate tabular matter." Such persons are not competent judges. It is for medical statisticians, including in that term not only the medical staff of the Ministry of Health but all medical officers of health, and for representatives of the medical profession as a whole to decide what is of value. We must say frankly that the creation of any suspicion that the whole of the data of mortality were no longer made available for the ordinary citizen would be, in our opinion, a great evil, and would play into the hands of anti-medical propagandists. We regard these blue books as important instruments of public education. They are instruments of which we should be proud: our official vital statistics are the best in the world. The medical profession regrets that they have not hitherto been utilized so fully as they might be by the general public, but cannot agree that this neglect ought to be

accepted as a reason for still further restricting the unofficial circulation of the means of acquiring knowledge. A truer economy would be to seek means of increasing the demand. Were the publicity methods of the Stationery Office modernized, the reports of the Registrars-General would no doubt not become "best sellers," but they might find many more purchasers than they have at present.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual meeting of the Medico-Psychological Association of Great Britain and Ireland was held on July 19th, 20th, and 21st in Edinburgh, on the first and third days at the Royal College of Physicians, and on the second day in the physiology lecture room of the University. Professor G. M. Robertson of Edinburgh was elected president for the year 1922-23; a full summary of his presidential address was given in the JOURNAL of July 22nd (p. 134). At the opening meeting Dr. C. Hubert Bond, who was in the chair, referring to the committee which had been appointed in connexion with the True case, said that the Medico-Psychological Association some years ago had come to the conclusion that it was impossible for it to offer advice of utility with regard to such cases; circumstances had changed since then, however, and it hoped now to be able to offer something, if it were desired, to that important Committee. It had therefore been decided by the association to form a committee and to discuss and classify the medical aspects of the plea of insanity in criminal cases. Dr. A. Ninian Bruce read a paper on "The outside and the inside treatment of early cases of mental disorder." Professor G. M. Robertson presided at the morning and afternoon sessions of the second day, when in the morning Sir Edward Sharpey Schafer gave an address on "The influence of the endocrine glands on the nervous system." Sir Frederick W. Mott read a paper on "The investigation of the relationship of the reproductive and endocrine glands to mental diseases," and Dr. J. J. Graham Brown gave a paper on "Observations relating to the sympathetic and parasympathetic systems." At the afternoon session Dr. David Orr gave an address on "The inter-reaction of the endocrine, sympathetic, and central nervous systems in organismal toxæmia, with special reference to emotional disturbance"; papers were read by Professor J. C. Meakins on "The influence of chemical substances of the endocrine glands and nervous system," and by Dr. W. H. B. Stoddart on "The mental factor of some endocrinopathies." On the concluding day of the meeting Dr. Chalmers Watson gave an address on "The treatment of intestinal toxæmia," which was followed by an interesting discussion, in which Sir Frederick Mott, Dr. H. Crichton Miller, and others took part.

SIR NORMAN MOORE.

At the comitia of the Royal College of Physicians of London held on July 20th the President, Sir Humphry Rolleston, announced that Lady Moore had offered to present to the College the portrait of Sir Norman Moore by Walter W. Russell, A.R.A., which has been on view this summer at the Royal Academy. The offer was gratefully accepted. This portrait shows Sir Norman Moore seated, and wearing the robe of black velvet and gold lace of the President of the College—the office held by him for four years, 1918 to 1922. An earlier portrait, by R. G. Eves, which was exhibited at the Academy some years ago, is reproduced as a photograph frontispiece to the first volume of his great work, *The History of St. Bartholomew's Hospital*; for that he wore the black bonnet and scarlet gown of a Doctor of Medicine of the University of Cambridge. It is fitting that the portrait that will hang on the walls of the Royal College of Physicians should depict Sir Norman Moore in the Presidential robe. He has been a Fellow for forty-five years, and none of his illustrious predecessors have served the College with greater distinction, or with a higher regard for its honour. This picture will remind future generations that the learned physician was a living force in the intellectual world of medicine during the first quarter of the twentieth century.

SIR MALCOLM MORRIS'S GOLDEN WEDDING.

A LUNCHEON to celebrate the golden wedding of Sir Malcolm Morris and Lady Morris was held on July 18th at the Trocadero Restaurant, London. Sir George Nowman presided, and was supported by Sir James Michelli, Dr. J. J. Pringle, Dr. J. J. Perkins, Mr. J. Grant Ramsay, and Dr. C. M. Wilson. The Chairman, after reading letters of regret for their absence from the Archbishop of Canterbury and Sir StClair Thomson, presented to the guests an inscribed George III silver tea service, together with a volume containing the signatures of the subscribers. The health of Sir Malcolm and Lady Morris was proposed by Dr. Pringle, who spoke of his unsullied friendship of forty years, and of the prominence of Sir Malcolm in the British dermatological world. Sir Malcolm Morris, who spoke with great emotion, referred to the early struggles of his life, when he was the youngest of fifteen children, and he told of his resolution at the age of 17 to enter the medical profession. Turning to Sir James Crichton-Browne, who was present at the luncheon, Sir Malcolm Morris told of how he had made his acquaintance in connexion with work at the mental hospital at Wakefield: "I got from him a bacillus of ouergy; that bacillus is still active, and its cultivation is entirely due to the co-operation of Lady Morris." Lady Morris also briefly responded, and a vote of thanks to the Chairman, proposed by Sir Thomas Hordor, brought the very happy proceedings to a close. Amongst those present were the Columbian Minister, Lord and Lady Dawson, Lord Gorrell, Sir W. H. and Lady Willeox, Sir John and Lady McFadyen, Sir Henry and Lady Gauvain, Sir Arthur and Lady Conan Doyle, Sir Anderson and Lady Critchett, Sir Arthur Newsholme, Sir Squire Sprigge, Sir J. Thomson Walker, Dr. Mary Scharlieb, Mr. E. Rock Carling, and Professor C. C. Choyee, and several members of Sir Malcolm Morris's family.

MEDICAL LITERATURE FOR RUSSIAN DOCTORS.

In a note on the Fund for Russian Doctors published in our columns of July 15th it was said that a recent message from Moscow stated that Russian doctors were in great need of modern medical literature, as their supply had been cut off for several years. British doctors who could spare files of medical journals for the past three years were invited to turn them over to the American Relief Administration for distribution. We are informed that this notification went further than was intended, and that the American Relief Administration in London finds itself unable to deal with the very numerous and generous offers it has received from medical men in this country. It proposes to limit its efforts in this respect to obtaining week by week spare copies of English medical journals, which it could then dispatch at short intervals by its couriers to Russia. The arrangements for this are not yet completed, and it is hoped to make a further announcement shortly. The total amount received by the British Medical Association for the Russian Doctors' Relief Fund down to July 24th was £1,503 0s. 11d.

THE REGISTRAR-GENERAL'S REPORT FOR 1920.

THE eighty-third annual report of the Registrar-General of Births, Deaths and Marriages in England and Wales has been published as a blue book of 531 pages.* The figures in each respect are remarkable. The marriage rate was 20.2 per 1,000, which is the highest recorded, being 0.5 above that of the preceding year, and 4.8 above the average of the last ten years before the war. The birth rate was 25.5 per 1,000, or 7.0 above that of the preceding year, which was the highest since 1909. The death rate was 12.4 per 1,000, or 1.3 below that of the preceding year, and is the lowest recorded. The number of deaths, 466,130, was the smallest for any year since 1862, when the population was little more than half that of 1920. As the number of births was 957,782, the natural increase was 491,652, as compared with 188,235 in the previous year, and 50,800 in the year before

* To be purchased through any bookseller or directly through H.M. Stationery Office. (£1 net.)

that. The amount of this excess, the largest in the history of the country, was due to the temporary rebound of the birth rate following demobilization, in conjunction with the exceptionally low death rate. It is expected that the latter factor will be repeated—the provisional figure for 1921 is even lower. A repetition of the 1920 birth rate is deemed unlikely. On ratio of population, however, the excess does not represent an absolute record; the birth rate for the whole quinquennium 1876-80 (when it reached its maximum) was 14.5, whereas in 1920 the excess was only 13.1 per 1,000 of population. The proportion of males to females born was 1,052 per 1,000, and so it continued much above pre-war experience. Dr. Stevenson, the superintendent of statistics, is able to point to another big step forward shown in the figures relating to infant mortality. The rate fell in 1920 to 80 deaths per 1,000 births, against 89 in 1919, which was the lowest previous corresponding rate. It is pointed out, however, that this improvement is partly due to the large increase of the birth rate during the year. A method adopted this year to correct such fallacy raises the rate from 80 to 85, which is, however, highly encouraging as an improvement on the lowest corresponding rate for any previous year (91 in 1916 and 1917). Under this method of tracing the mortality quarter by quarter it is found that the decline chiefly occurred during the second half of the calendar year. The year 1920 shows a rise in deaths from most forms of epidemic disease as compared with the rate in 1919, which was unprecedentedly low. The increase in respect of measles and whooping-cough is considerable, but slight in other cases; the only decrease is from enteric fever, which for the sixth year in succession was the lowest ever recorded in the country. In regard to tuberculosis it is satisfactory to learn not only that the death rate was considerably lower than in any previous year, owing to the circumstances of war and the pandemic of influenza, but that the ground lost in progressive reduction has now been substantially regained. The opinion is given that this advance will probably be found to have been kept up in 1921, but not materially improved. The increase in the birth rate is again mentioned to explain a slight increase in the crude mortality from syphilis, to which the deaths of infants normally contribute in a preponderating degree. But when the increase is discounted by standardization, the mortality attributable to this cause is found to have declined. The more general death rate under this heading shows a considerable fall since 1917. In regard to cancer mortality, some further increase is reckoned to have occurred in 1920. This statement is applied more to males than females, whose rate has hardly advanced during the last eight or ten years. The deaths allocated to encephalitis number 861, as against 663 in the year 1919, 366 in 1918, and 329 in 1913. Included in the table are 471 deaths ascribed in 1920 to encephalitis lethargica, as against 290 in 1919, 4 in 1918, and none in 1913. The total number of deaths under or connected with the administration of anaesthetics (366) is considerably higher than in any of the nine preceding years, for which alone the complete figures are available. The number is said to have been fairly constant, having varied only between 261 in 1915 and 306 in 1916. The chief increase in any one age group is in infancy, 28 such deaths having been reported in 1920 at ages under one year as against 11 in 1919. Of the 26 male infants, 11 were being operated on for hernia or intestinal obstruction, 8 for phimosis, and 3 for cleft palate. It is pointed out that the assumption must not be made that in all the cases death was due to the anaesthetic, though in many, owing to the nature of the condition occasioning the administration, there may be strong presumption. With the aid of the preliminary report of the census issued in August, 1921, the population in the middle of 1920, upon which figures are based, was reckoned to comprise 17,866,000 males and 19,658,000 females. A very large number of tables are appended, and one of these shows that the death rate of both sexes was very low in old age as well as at other periods of life. As usual, the volume includes classified statistics of various counties.

DYSMENORRHOEA AS AN INDUSTRIAL PROBLEM.

In view of the large and increasing employment of women in industry, the industrial aspect of dysmenorrhoea, perhaps the commonest of all female ailments, is a matter which merits serious consideration. The *Journal of Industrial Hygiene* for June, 1922, contains a preliminary note on dysmenorrhoea as an industrial problem, by Dr. Samuel R. Meaker of Boston, U.S.A. It is highly suggestive and indicates the direction in which further investigation for the alleviation of the condition is necessary. Dr. Meaker investigated the industrial incidence of dysmenorrhoea with a view to determining its effects upon industry and the best methods for dealing with it. Industrial crippling from dysmenorrhoea occurred in three ways: (1) The girl remained at work, but with lowered general efficiency; (2) the girl was incapacitated for a short period of the day; (3) the girl was absent for a full day or longer. The first group does not entail any considerable industrial loss, while in the second group rather over 10 per cent. of the girls were found to seek relief at the rest room or hospital during any given month. Half of these girls were able to return to work after a hot drink and a rest of from ten to fifteen minutes, so that the amount of time lost was negligible; somewhat less than one half of them lay down for periods averaging about two hours; about one-eleventh of this group were sent home for the remainder of the day, the industrial loss in each such case being one day. The third group—those absent for a full day or longer—was found to be chiefly responsible for industrial loss; it was estimated to constitute more than 1 per cent. of the total time of the employees. Dr. Meaker considered that much could be effected by providing proper medical care for those seeking relief at work (Group 2) and by education among those who had to stay away from work (Group 3). Women, he says, are amazingly backward about seeking medical relief for their menstrual difficulties; the subject could, he thinks, be brought to the notice of employees at the time of their engagement, and upon reporting at hospital; in this way nearly four-fifths of the female staff would be educated upon the problem during any one year. It was believed that once the industrial aspects of dysmenorrhoea and the possibility of successfully handling the problem were realized by employers their co-operation in establishing facilities for care and treatment would be assured. The greater part of the suffering from dysmenorrhoea could be prevented by simple measures, and in most cases without pelvic examination.

RADIOLOGY OF THE CHEST IN CHILDREN.

In May, 1920, a small committee, consisting of three clinicians and three radiologists, was appointed by the National Tuberculosis Association of the United States to report on the x-ray and clinical findings in the chests of normal children from 6 to 10 years of age. The committee was asked to define a standard in order to facilitate by contrast the interpretation of the abnormal signs characteristic of active disease, particularly tuberculosis. Working in pairs at three different universities the members of the committee examined over 500 children of all grades of society and representative of both urban and rural communities; they were free from symptoms of disease, and of approximately normal height and weight for their respective ages. After nearly two years' work a full meeting of the committee was held, the results of each pair were correlated, and the report now issued drawn up in accordance with the unanimous expression of opinion of all those engaged in the research. From the clinical standpoint great stress is laid on the variable nature of the percussion note in children. In some cases it is fuller, more tympanitic, of higher pitch, and of greater resilience than that noted in adults, while in others it is indistinguishable in quality from that elicited over the lungs of fully grown individuals. Similarly with the breath sounds; though generally possessing a harsh sharp character with prolonged expiration they by no means

frequently display the usual vesicular murmur of adult life. In more than 50 per cent. of the children in which this latter type of breathing was heard examination with the x ray gave findings similar to those obtained by a study of normal adult chests. So close, in fact, was the agreement between the clinician and the radiologist that it was found possible to designate the chest of normal children as of "puerile" or of "adult" type. These variations and those of the percussion note are more generally found in children with a history of previous infection of the respiratory tract. It was noticed that after such infections as measles and pertussis areas of increased density radiating from the hilum to the base occurred with great frequency; these were observed even in uncomplicated cases, indicating that a general inflammatory process of the whole respiratory passages may be a common feature of these two diseases. That such shadows are evidence of healed processes and not of active lesions is indicated by the fact that they may remain unchanged and without the development of clinical symptoms for three to five years at least. D'Espine's sign as denoting the presence of enlarged tracheo-bronchial glands was found to be of little value, while Enstace Smith's sign is so generally elicited in normal children as to deprive it of diagnostic importance. Among the more important conclusions reached by the committee three may be stated. The first is that the normal chest of the child is, from the radiological standpoint, subject to such wide variations within normal limits as to be beyond the possibility of exact description. The second is that the conglomerate shadow commonly called the hilum shadow, when found lying entirely within the inner third or zone of the lung area, can be disregarded (or regarded as normal), except where it is made up of a solid mass of homogeneous shadow giving undoubted evidence that it represents a growth or mediastinal plenisy. The third conclusion is that calcified nodes at the root of the lung, without evidence of lung disease, are of no significance except as a possible evidence of some healed inflammatory condition, possibly but not necessarily tuberculous. They are a common finding in normal chests. It is stated, further, that persistence of the bronchial shadows to the peripheral zone of the lung may be due to a variety of conditions, past or present, of an inflammatory nature or otherwise, but is not necessarily indicative of tuberculosis. In congratulating the National Tuberculosis Association on the thoroughness of the work conducted under its auspices, we may remark that once again we meet with an example of the extraordinary value of the co-operation of two classes of workers proceeding along different lines in elucidating problems which, regarded from one or other side alone, remain obscure.

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE.

THE International Congress of the History of Medicine held in London last week was a great success. It came to an end on Friday, July 21st, when a farewell banquet was held at the Hotel Cecil. We published last week (p. 145) an account of the opening of the proceedings, but owing to the pressure of matter from the Annual Meeting of the Association at Glasgow are compelled to defer publication of the remainder of our report until next week.

BEER AND LEAD POISONING.

INFORMATION has reached us of several cases of lead poisoning among men which it is considered are due to the drinking of beer. A modern development of the equipment of beerhouses is the provision of stoneware or earthenware troughs along which the beer flows or may remain for some time. It is suggested that the lead glaze on the troughs is so acted upon by the beer that a sufficient amount of lead is imbibed to result in definite symptoms of lead poisoning.

Owing to the pressure of matter from the Annual Meeting in Glasgow the issue of the *EPITOME* is suspended for this week.

ANNUAL MEETING NOTES.

THE Annual Representative Meeting of the British Medical Association opened in Glasgow on July 21st with Dr. R. Wallace Henry in the chair. During the morning Sir William Macowen paid a visit to the meeting and welcomed the Representatives to the City of Glasgow on behalf of the Executive of the Reception Committee. A little later Sir Donald MacAlister attended and welcomed the British Medical Association to Glasgow on behalf of the University, of which he is Vice-Chancellor and Principal. Reports of the proceedings on that day and on Saturday, July 22nd, and of part of the proceedings on Monday, July 24th, are published in the SUPPLEMENT this week, and to them members are referred for a detailed account of what happened. We here refer only to a few outstanding matters.

The British Medical Association, being conterminous with the British Empire, is experiencing certain difficulties, similar to those encountered by the British Government, in the adjustment of its constitution to the fact that the Dominions have grown to man's estate. Last year one of the most anxious matters with which the Representative Meeting had to deal was the nature of the relations which might best be maintained with the Branches in the great Commonwealth. With the assistance of Dr. Todd, who had come from Australia to express the view of the Branches there, a solution was then found, and the Representative Meeting this year opened with the reading by the Chairman of a cable message conveying the best wishes of the Federated Australian Committee for a successful Representative Meeting. Early in the meeting Dr. J. F. Wilkinson, the Representative of the Victorian Branch, made a short speech, which was listened to with great pleasure by the Representative Meeting. He expressed the thanks of the Federal Committee and the members of the Australian Branches generally for the very friendly way in which they had been met in this matter, which they regarded as one of very great importance. The proposals made would enable them to work out their medical affairs in the way which seemed to them best, but without any break from the parent Association, which was for them a most vital factor. They desired that nothing should be done which would in any way weaken the link that bound them to the parent Association. The Representative Meeting then passed to a consideration of the relation of the British Medical Association to the organization of the medical profession in South Africa, a matter which presented some resemblances, but also some serious points of difference from the problem that arose in Australia. The Chairman of the Organization Committee, Dr. Morton Mackenzie, brought forward a resolution, which, with certain amendments, was eventually adopted; but before this stage was reached the meeting heard an interesting speech from Dr. Barnard Fuller, the Representative of the Cape of Good Hope Western Provinces Branch. He said that though Cape Colony was content with existing arrangements, there was in South Africa, not only among medical men, but among the general population, a large section to whom anything with the prefix "British" was distasteful. The difficulties were great, and he had found it far from easy to decide what would be the wisest course to take. Those who were most anxious to keep in intimate touch with the British Medical Association realized that in South Africa it was necessary to go warily both in general and in medical politics. He looked forward to a new association which would bring all South African medical men within its discipline and would be linked up with the British Medical Association. The resolution adopted by the Representative Body on July 21st reiterated the opinion it had previously expressed in favour of federation of any purely medical body or bodies representing substantially an ex-branch or group of ex-branches of the British Medical Association outside Great Britain which desired it, and instructed the Council to confine the discussion of the scheme proposed to the South African Committee or any alternative scheme suggested by it.

The first part of the session of Friday afternoon was occupied by an animated discussion on the question of professional secrecy. It may be remembered that the Annual Representative Meeting last year expressed the view that the Association should use all its power to support a member of the British Medical Association who refuses to divulge without the patient's consent information obtained in the course of his professional duties, except where it is already provided by Act of Parliament that he must do so. This resolution was referred to the Council with an instruction that it should be submitted to the Representative Meeting this year with a view to considering the propriety of its becoming the policy of the Association. When the position came to be looked into by the Council various difficulties were encountered, and in its annual report the Council recommended that the minute should be rescinded and suggested an alternative declaration. The matter was accordingly brought before the Representative Meeting this year by the Chairman of the Central Ethical Committee, Dr. R. Langdon-Down, who set out fully the reasons which had induced the Council to come to the conclusion that it was undesirable to make the resolution of last year a declaration of the policy of the Association. On behalf of the Council he proposed an alternative form. This was accepted with only seven dissents. Afterwards an extension put forward on behalf of the Kensington Division by Dr. Buttar was also accepted, and the resolution as finally adopted set out that since in the opinion of the Representative Meeting it is an essential principle of medical conduct that information obtained in connexion with the treatment of patients should not be divulged without the consent of the patient concerned, the Annual Representative Meeting declared its opinion to be that the proper preservation of professional secrecy necessitates a measure of special consideration being recognized for medical witnesses in courts of law, above and beyond what is accorded to the ordinary witness.

Later the meeting turned to the consideration of the sections of the Annual Report of Council dealing with National Health Insurance, and the recommendations of the Council were submitted by Dr. Brackenbury, Chairman of the Insurance Acts Committee. Two important decisions were reached: the first, which was carried unanimously, affirmed the Representative Body's insistence upon the continuance of the system of negotiation which has prevailed since the coming into force of the National Health Insurance system—namely, direct negotiations between the Government and the profession without the intervention of any third party—but at the same time expressing readiness to welcome the co-operation of all those interested in the development of the best possible medical service for insured persons. The second resolution, which was carried on a roll call by 81 to 21, stated that in the opinion of the Representative Body the measure of success which has attended the experiment of providing medical benefit under the National Insurance Acts has been sufficient to justify the profession in uniting to ensure the continuance and improvement of an insurance system. It will be remembered that the Conference of Panel Committees last October unanimously passed a resolution in similar terms.

Monday morning was occupied by the Representative Meeting in the consideration of the sections of the Report of Council relating to the finances of the Association and to the work of the Medical-Political Committee. It has been found necessary to postpone the report in the SUPPLEMENT of the proceedings on these matters in order to make room for the conclusion of the report of the discussion of the hospital policy of the Association, which occupied the greater part of the afternoon session on Monday.

The subject which occupied more of the time of the Representative Meeting than any other was the hospital policy of the Association. It is not surprising that the Association has great difficulty in exactly defining its position. The fact seems to be that the practice of medicine is going through

a period of change which may be called, without exaggeration, revolutionary. It is not merely that the financial distress of the hospitals has become more acute than before, nor only that the insurance scheme introduced some ten years ago is lopsided, since it does not make provision for in-patient treatment in hospitals; but it is also that the increasing complexity of medicine has compelled the adoption of what is called the "group system" of treatment in all classes of practice. It had been beginning to develop rapidly in large hospitals before the war, and the movement was greatly accelerated by the war, when the medical officer in charge of a patient could obtain with ease the assistance of the combined investigations by physician, surgeon, radiologist, chemist, and bacteriologist. At present the only way in which these combined opinions can be obtained is, in the case of a patient who is not rich, to go to a hospital; while a rich patient must either go the round of the specialists or enter some private institution which will undertake a complete examination for a lump fee; and of such institutions there are not many. We will not here attempt to give a summary of the long and rather complicated discussion, the report of which in the *SUPPLEMENT* should be read by every member of the profession. It will be noted that the Association once more recorded its belief that the voluntary method of administration of the voluntary hospitals of the country is to the advantage of the public, medical science, and the medical profession, and should be maintained; and further, that the essence of the voluntary system is the independent and voluntary management, which is not necessarily related to conditions of service of the medical staff. It was also affirmed that the voluntary hospitals have grown up on a general understanding between the subscribers, the board of management, and the members of the honorary medical staff, that both funds and services were placed gratuitously at the disposal of those unable to pay for adequate medical treatment, but that the understanding for gratuitous service was mutual and reciprocal. This being so the general tendency now existing for the exaction of payment, however small, from the patient, necessarily modified the original understanding and fundamentally altered the basis of the relation between the honorary medical staff and the subscribers. The proposal for the formation of staff funds gave rise to much discussion and disclosed that there were two opposed and, as it would appear, fairly evenly balanced opinions in the meeting. An amendment by Dr. Brackenbury was carried but was not put as a substantive motion, the suggestion of the Chairman of the Hospitals Committee that the point at issue should be referred back to the Council being accepted. Dr. Brackenbury's amendment was to the effect that where payments of patients were made by rate aid or State aid, and where in other cases payments were of an amount exceeding the cost of hospital maintenance and accommodation, such charges should be considered to include payments towards maintenance and treatment and a percentage of all such payments passed into a fund, which should be at the disposal of the honorary medical staff.

It is interesting to record that a conference on the subject has recently been held between representatives of the medical staffs of ten of the London teaching hospitals; the result of this conference has just been announced, and it appears that it arrived at conclusions similar to those so far reached by the British Medical Association. The hospitals represented were St. Bartholomew's, St. George's, Guy's, King's College, St. Mary's, the Middlesex, St. Thomas's, University College, the Westminster, and the Royal Free. The first resolution, adopted without a dissentient, was: "That under present conditions in the case of patients who contribute towards, but pay not more than, the whole cost of their maintenance in a voluntary hospital, it is undesirable that any portion of such contribution should be allocated to a staff fund." The second resolution, from which Guy's, Middlesex, and University College dissented, was: "That when the State, a municipal or other public body pays towards the accommodation, maintenance,

and treatment of a patient or group of patients in a voluntary hospital, a percentage of such moneys should be allocated to a staff fund." A third resolution, from which Guy's dissented, was also adopted, to the following effect: "That when a special clinic is held by a member of a hospital staff for the treatment of patients sent by the State, a municipal or other public body, the member of the staff taking such a clinic should be adequately paid."

The business of the Annual Representative Meeting was brought to a satisfactory conclusion soon after 3 p.m. on Tuesday, July 25th. That no curtailment of the time allowed to speakers had been found necessary was matter for congratulation in view of the complex and contentious nature of much of the agenda. On Tuesday, indeed, from the presentation of the Report under "Science," by Sir Clifford Allbutt, to the votes of thanks with which the meeting closed, Representatives had little to do beyond recording approval of the year's progress under the several heads remaining. That approval was especially wanted in connexion with the work of the Dominions and the Scottish Committees. One point only provoked discussion, and on that point, the compulsory retirement of Senior Surgeon Commanders of the Navy Medical Service without compensation, the meeting, whilst expressing cordial approval of past action, left the Council with no uncertain mandate for the future.

Great efforts have been made this year to ensure the success of the Annual Exhibition of instruments, apparatus, drugs, food, books, and medical accessories, which has long been a feature of the annual meetings of the British Medical Association. The exhibits at Glasgow have been arranged in a portion of the large Kelvin Hall, which adjoins the grounds of the University; a better building for this purpose can scarcely be imagined. The firms exhibiting number nearly eighty, and they have succeeded in bringing together a great deal of material of much practical interest to members of the medical profession. An account of the exhibits will appear in subsequent issues, but we may note here that the opening ceremony, presided over by the President, Sir William Macewen, on Tuesday morning, July 25th, was attended by the Bailie Allan, Sir Clifford Allbutt, the officers of the Association, and a very large number of Representatives, who were impressed with the general arrangement of the stalls and the good taste shown by the firms in displaying their goods.

The Municipal Departments of the Corporation of Glasgow arranged elsewhere an interesting exhibition. It grew out of a desire expressed by Sir William Macewen that the Public Health Department of Glasgow should illustrate the several directions in which municipal effort tends to further the health of the community. The suggestion was enthusiastically taken up by the Health Committee in the first instance, and thereafter by the other committees whose work runs on parallel lines, so that altogether twenty-two sections of Corporation activity were illustrated. We propose to publish a detailed account of this exhibition next week.

On the afternoon and evening of Sunday, July 23rd, a large number of Representatives and their wives and families had a delightful sail on the River and Firth of Clyde in the ss. *Skirmisher*. The afternoon was fine and the trip was greatly appreciated. Starting from Yorkhill Quay, the steamer passed the great shipyards of Clydebank. Next, the visitors saw Dumbarton Castle and had a peep at Ben Lomond in the distance; they then sailed past Port Glasgow and Greenock, and traversed Loch Long and Loch Goil, in the midst of the beautiful West Highland scenery. Nearing the head of Loch Long, the steamer turned and proceeded seaward as far as Hunter's Quay, returning thence up the Clyde to Glasgow, Yorkhill Quay was reached at nine o'clock, after seven hours' keen enjoyment. Tea, supper, and music were provided on board, and the general arrangements were perfect.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Milk and Dairies (Amendment) Bill.

THE Second Reading of the Milk and Dairies (Amendment) Bill, which had come down from the Lords, was moved in the Commons on July 19th by Sir A. Mond. The measure will further postpone the operation of the Act of 1915, which would otherwise come into force next September. The application of the original Act was delayed on account of the war, and the Minister said that one reason why it was not to be applied now was that it would require a large staff and place heavy duties upon county councils, involving a charge of something like £800,000 a year, rising to a million sterling, for administration. Moreover, it would put expenses on landlords and farmers which, in their present financial position, they were not ready to carry out. Farmers could not be compelled to produce milk, and if conditions were too onerous would not do so. The present bill was intended to encourage the supply of good milk, the policy being to endeavour to secure it by a form of persuasion rather than by compulsion. The best form of persuasion lay with the consumer. If he insisted on having a better standard of article he would get it. Practical experience shows this to be the case. Local authorities already possessed considerable powers for securing sanitary conditions in production, storage, and distribution of milk. The Milk and Dairies Order of 1885 gave very large powers, and if they were more generally enforced much more would have been done than was the case at present in the direction of obtaining clean milk. The orders of 1885-86 and 1899 provided for the registration of all dairies and milk shops, the lighting, ventilation, cleansing, drainage, and water supply of premises, and for precautions against infection or contamination. Section 6 of the Sale of Food and Drugs Act, 1885, made it an offence to sell, to the prejudice of a consumer, an article of food which was not of the nature, substance, and quality as demanded. Though the order of 1885 required local authorities to keep registers, it gave no power to revoke registration in any case outside London. It was proposed in the present bill to give such power, which would be extremely useful for enabling authorities to keep these places under better supervision and control. To guard against arbitrary revocations various provisions for reference to the courts by way of appeal were made. A main feature of the present bill was to encourage grading up. At present the Ministry had thirty-five grading stations in which a very strict inspection was made with tuberculin tests in regard to the cattle used. The number of licences for the certified grade and Grade A had increased from 17 in March, 1920, to 57 in July, 1922. But the milk so standardized was rather a luxury article than one useful to the mass of the people. He proposed to try and provide a system under conditions by which any reasonably careful farmer should be able to supply this quality of milk without any great additional cost. The aim was to set up, as a standard article, milk which for health purposes would be satisfactory. The grading would be done by orders to be drawn up when the bill was passed and, of course, submitted to the House. He wanted to get milk which was free from tuberculosis bacteria. It was not the case that every cow which reacted to the test gave tuberculous milk. The Medical Research Council, at his instigation, was carrying on an elaborate investigation into the whole question of the value of tests. He proposed to go on the lines of testing the milk rather than the cow. He was laying down a standard of a bacteriological kind in the milk test rather than dealing with the animal. In Clause 4 provisions were introduced to prohibit the addition of colouring matter or water. This was a continuation of a food control order of 1921 which would lapse on September 1st if not embodied in the bill. Under the clause it was made an offence to sell, or offer for sale, adulterated milk. Under Clause 5 it was made an offence for any persons knowingly to sell milk from a cow with tuberculosis of the udder. The penalties were severe. This continues Article 15 of an order of 1885 as amended in 1889. Clause 8 gave the Minister power to make regulations to prevent danger to health from imported milk. This was not a question of condensed but of fresh milk. Condensed fell under another category. The question of the standard of condensed milk was one more of food value than of liability to spread tuberculosis. Regulations not yet settled might lay down some standard, but he would not, at the moment, like to say what they should be. Under Clause 11 powers might be exercised by a county council where the district council failed to exercise them. The Minister of Health might, after inquiry, determine that all or any such powers should be or as he might direct. Up to the present the enforcement of orders had been very unequal. Not only would the orders

have to be laid before Parliament, but consultations would have to take place between himself and the Minister of Agriculture as to their framing.

Mr. Acland, who, as chairman of the Agricultural Organizations Society, some months ago called a conference which broadly favoured the lines of this bill, gave the measure support but reserved the right of criticism in regard to certain matters. Referring to Clause 5, designed to prevent the sale of tuberculous milk, Mr. Acland said he had seen it stated as the opinion of Dr. Raw that so long as children could get enough milk a certain amount of cow tuberculosis infection in that milk was not harmful, but might be beneficial, because it tended to immunize the children who took it from human tuberculosis. If that were so, it revolutionized very many previous ideas, and the House ought not to hurry too quickly in making regulations.

Sir Watson Cheyne remarked that milk might be a carrier of disease in two ways. It might carry typhoid, not through the cow having typhoid fever, but because the water used to dilute the milk might have come from an infected well or because the milkman himself has typhoid. So with diphtheria or scarlet fever. In the case of tuberculosis, however, the milk carried the germ of an extremely serious disease from a cow infected with it, and no pains should be spared to prevent that happening. The difficulty in getting agreement with agriculturists or dairy people for special precautions in regard to tuberculosis was extraordinary. He thought it was due to the want of appreciation of the real danger. He was of opinion that the word "knowingly," in the clause which laid down that no person should knowingly sell the milk of a cow suffering from tuberculosis of the udder, left a loophole for evasion, because anyone could say he did not knowingly sell such milk. Ignorance was not allowed to be an excuse in other matters, as, for instance, when a person was taken ill from ptomaine poisoning from food eaten in a restaurant. He was afraid also that, although there was not much danger in the milk of a cow even if it suffered from a general tuberculosis disease unless the udder itself was affected, by putting these words into the bill the farmer would be misled into concentrating attention on the one question, and forget to see whether the milk was affected. Diagnosis for tuberculosis disease by external banding of the udder was almost impossible, and plenty of expert veterinary evidence would be given of contradictory character. He thought that a conviction could not be obtained unless there was a provision in the clause against milk containing tubercle bacilli. The farmer could know quite easily whether the milk was tuberculous by having it examined microscopically. Urging the importance of getting this security Sir Watson Cheyne said that he had lately met a doctor who had practised in America in one of the States where very stringent precautions were enforced, and during several years of private practice there with visitation at the large hospitals, that gentleman said he had never once seen a case of tuberculous glands in the neck. Great Britain had fallen behind in attention to this matter. If a milkman were to sell milk containing arsenic it would be thought a terrible thing, even though done accidentally. Why should he be allowed to sell milk filled with tubercle bacilli of the most virulent description?

Mr. Myers deplored the postponement of the operation of the Milk and Dairies Act of 1915, and believed that many of its provisions could be carried through without extra expenditure. He was strongly in favour of the provision in the 1915 Act whereby authorities might combine to employ a veterinary surgeon to look after dairy cows. He also objected very much to the word "knowingly" in Clause 5. Mr. Myers further touched upon the sale of low-grade milks which come from separators, and very much regretted there was no provision to enable authorities to undertake the supply of milk.

Dr. Addison described the bill as "a milk and water bill," his view being that it was inadequate for the purpose. As soon as public opinion was instructed it would begin to make its influence felt all along the line as far as the cowshed. The Act of 1915 tried to approach the problem to some extent from that end. He ridiculed Clause 5, holding that it would be inoperative. The only part of the bill which would, he thought, be of any use was that part which provided for grading, but the rest would give the public a false sense of security.

Viscount Elveden warmly supported the bill, and after some other speeches Sir A. Mond replied. He defended Clause 5, insisting that at any rate it would put the farmer on his guard against selling milk from cows which had tuberculosis of the udder. The Minister then explained broadly what was proposed in regard to grading. Certified milk would be graded very much on the present lines. Every animal would be subjected to the tuberculin test before being admitted to the herd, and certified as a non-reactor. Every three months the herd would be examined by a veterinary surgeon, and the

milk examined for tubercle bacillus. If there was evidence of tuberculosis the animal would be withdrawn from the herd. If milk from the group showed evidence of tuberculosis, the whole group would be withdrawn until the affected animal was identified. Milk was to be bottled on the farm immediately after production and delivered to the consumer within two days of production, and must not contain more than 30,000 bacteria per cubic centimetre or any *Bacillus coli* in a tenth of a cubic centimetre. In the case of Grade A milk the health of the herd was to be the same as with certified milk except that there would be no tuberculin tests. The milk might be pasteurized, but if so it must be so sterilized. These limitations involved the use of per cubic centimetre. These limitations involved the use of sterilized vessels with careful regard to cleanliness, especially to ensure freedom from manual contamination. The examination would be a test of tuberculin milk. People who ask for Grade A milk would get milk which they could trust. If they continued to call for Grade A milk other grades would not be sold. The consumer would be interested. The bill was read a second time.

Pensions Appeals.—Sir F. Hall asked, on July 17th, whether officers and men whose cases came before a medical appeal board were now entitled to appeal from the decision of such board to another tribunal. Major Tryon said that Sir F. Hall appeared to be under a misapprehension as to the respective functions of the medical appeal board and assessment appeal tribunal. The assessment appeal tribunals, which were constituted under Section 4 of the War Pensions Act, 1921, dealt only with appeals against a decision of the Minister that the award made in a given case was final. The medical appeal board dealt with appeals against a decision made by other medical boards of the Ministry. They decided matters of assessment only, and did not pronounce as to the finality of the awards. There would consequently be no ground of appeal directly from the medical appeal board to the assessment appeal tribunal. When the finding of a medical board was made final by the Minister, the pensioner was so notified, and was at the same time informed fully of his right of appeal to the appeal tribunal. Lieut. Colonel Watts-Morgan asked whether it would be correct to say that the assessment appeal tribunal was set up as recently as five weeks ago, and that as many as a hundred cases were now waiting in South Wales, unable to get any sort of appeal or assessment? Major Tryon said these final awards were only just now beginning to be given. The tribunals were ready to receive appeals, but so far very few had been made, and he understood that they were being dealt with satisfactorily.

Insurance Patients: Drugs and Medicines.—Sir John Leigh asked, on July 19th, what, if any, precautions were taken against the supply of drugs and medicines of inferior quality to panel patients by retail chemists; and whether the Minister of Health was aware that such patients were frequently informed that they could have drugs and medicines of superior quality by paying for them? Sir John Leigh said that tests were made from time to time to ensure that prescriptions were correctly dispensed, and severe penalties had been imposed in cases where chemists had supplied drugs of a different quality from that ordered by the doctor. As regards the latter part of the question, the Minister said that if Sir John Leigh would give the particulars of any cases in which such statements had been made, whether by practitioners or chemists, inquiry would be made with a view to disciplinary action if the facts could be established.

A Coroner's Strictures.—Mr. Rhys Davies asked, on July 20th, whether the attention of the Minister of Health had been called to the strictures passed by the West Essex coroner on a doctor who, after being twice requested to do so, declined to attend a patient and when he arrived at the man's home found the patient on the point of death, and whether the doctor or the man was on the panel. Major Barnston (for Sir Alfred Mond) said the Minister was informed that at the time of the occurrence the patient was not entitled to medical benefit nor had he ever been on the list of the doctor concerned; he was an insurance practitioner, but there was no question of any failure to carry out his obligations under his agreement with the insurance committee.

Smoke Abatement Bill.—The Earl of Onslow moved the second reading of the Smoke Abatement Bill in the House of Lords on July 25th, suggesting that the latest stages should be deferred till he returns. The bill follows upon the report of the Smoke Abatement Committee, of which Lord Newton was chairman. It tends the Public Health Act so that all smoke and not merely black smoke may be dealt with. Larger fines are imposed for offences. The bill does not apply to Scotland. Lord Newton commended the measures as far as it went, but thought it inadequate. He transferred from small local authorities to county and district councils. He mentioned that England and Scotland were the first countries in Europe. In the London area 25 tons of fell per square mile per month. In Manchester alone the cost of washing collars due to the smoke was £50,000 a year. The bill was read a second time.

Brief Notes.
Sir Hamar Greenwood has stated that the question of the deduction of medical and surgical expenses in the case of members of the Royal Irish Constabulary injured in the exercise of duty is under consideration.

As the Port Sanitation Services are in large measure national services it has been decided to keep the provision by the Statute for Scottish port sanitation at £7,000. Under Section 23 of the Economy (Miscellaneous Provisions) Bill it was proposed to make the reduction of members in the Scottish Board of Health as recommended by the Geddes Committee. Sir Alfred Mond has informed Mr. R. Richardson that, under Section 49 of the Linnay Act, 1890, the Board of Control had full discretion to authorize any medical practitioner to visit a patient for the purposes of the section. In the exercise of their discretion the Board endeavoured to select medical practitioners who were, in their opinion, best qualified to act. The mere fact that the name had been submitted to them was in no way defamatory, and there was no reason for consulting the law officers of the Crown in the matter.

The Prime Minister states that the War Department at Washington has recently ordered the discontinuance of the manufacture of poison gas for the purpose of equipping the United States army, but Congress has sanctioned the continuation of research and experimental work in this connexion. The proposed expenditure by Great Britain for the coming year is £169,700 for research and experimental work. Otherwise the manufacture in this country is discontinued. The declared value of dental, surgical, medical, and veterinary instruments (except optical) registered as imported into the United Kingdom during the six months ended June 30th was £12,427. The value for the corresponding six months of last year was £20,592. Mr. Shortt has informed Dr. McDonald that licensed importers of cocaine are required to keep records of sales, and these are inspected from time to time. The records, however, cannot show the areas of eventual distribution of the drug, as it may pass through several hands before it reaches the medical practitioner, dentist, or other person by whom it is used. The National Health Insurance Bill went through Committee in the House of Lords on Wednesday, July 19th, and was reported on July 20th.

BEIT RESEARCH FELLOWSHIPS.

The trustees of the Beit Memorial Fellowships for Medical Research have elected the following candidates for Junior Fellowships of the annual value of £350. The usual tenure of a Junior Fellowship is three years:

Ernest Basil Verney, M.B., B.Ch.Cantab., M.R.C.P.Lond., Assistant in the Department of Physiology, University College, London. Proposed research—The physiology and pathology of urinary secretion. (Institute of Physiology, University College, London.)

Frank Cook, B.Sc., M.B., B.S.Lond., F.R.C.S.Eng., Gynaecological Registrar, Guy's Hospital, and Demonstrator of Pathology. Proposed research—The neuro-muscular apparatus of the uterus: observations on "pregnancy toxæmia," with particular reference to the acidosis factor. (Physiological and Pathological Laboratories of Guy's Hospital, London.)

John Lewis Rosedale, B.A.Oxon., M.A., Ph.D., Holder of Research Scholarship of Ministry of Agriculture and Fisheries since October, 1921. Proposed research—The chemistry of normal and pathological tissues, with special reference to the protein and nucleic constituents. (Chemical Laboratory of St. Thomas's Hospital Medical School, London.)

Reginald Hilton, B.A.Cantab., B.Ch.Cantab., now studying the theory and practice of artificial pneumothorax in the clinic and laboratory of Dr. Ritz, Laennec Hospital, Paris. Proposed research—The study of the blood gases in various stages of pulmonary collapse produced by artificial pneumothorax; the condition of the circulation in the collapsed lung. (Laboratory and wards of the Professorial Unit of St. Bartholomew's Hospital, The first two months to be spent at the Laennec Hospital, Paris.)

Arthur St.G.J. McC. Huggett, B.Sc., M.B., B.S.Lond., Demonstrator of Physiology at St. Thomas's Hospital. Proposed research—An investigation of the function of the placenta in relation to the passages of gases and other substances from the mother to the foetus, and the cause of foetal apnoea. (The Sherrington School of Physiology, St. Thomas's Hospital, and the Brown Anatomical Institution, Vauxhall.)

Victor Douglas Alkous, M.B., B.Ch., at present Research Student, Institute of Pathology and Research, St. Mary's Hospital, London. Proposed research—The investigation of the nature and properties of a hitherto undescribed substance which has a strong bactericidal, bacteriolytic, and bacterio-inhibitory action—named lysozyme. (Laboratory of the Institute of Pathology and Research, St. Mary's Hospital.)

The following Junior Fellows were elected to fourth year Fellowships of the annual value of £400:

David Keilin, D.Sc., who will study the life histories of protozoa pathogenic to insects; the life history, anatomy, and physiology of insects, at the Moltano Institute for Research in Parasitology, Cambridge, under Professor G. H. F. Nuttall, F.R.S.

Ivan de Burgh Dakin, who will study antivenenous block, at the Institute of Physiology, University College, London, under Professor Starling, F.R.S.

No appointments have yet been made to the Senior Fellowships of the annual value of £500, which are only open to junior and fourth year Fellows elected on or after January 1st, 1923. The usual tenure is for three years. All correspondence of candidates and Fellows should be to Sir J. K. Fowler, honorary secretary, Beit Research Fellowships, 35, Clarges Street, Piccadilly, W.

TOXIC EFFECTS OF ARSENOBENZOL PREPARATIONS.

REPORT BY THE SALVARSAN COMMITTEE.

THE Salvarsan Committee appointed by the Medical Research Council has recently issued its Report* on the toxic effects following the employment of arsenobenzol preparations. The committee was established in 1918 on account of a peculiarly high incidence of fatal jaundice following the use of "606" or "914" in certain military hospitals receiving syphilitic cases. However, in spite of the fatalities occurring about that time, accidents following the use of salvarsan and its congeners have, on the whole, been very much rarer in this country than on the Continent. Especially numerous have been the deaths recorded in Germany, and public opinion was so seriously disturbed at one time in that country that two separate official inquiries were made in 1914 and 1917 concerning the value of salvarsan treatment and the injurious effects which were alleged to follow its use. The findings of these German committees of inquiry were of importance, and they receive full consideration in the report issued by the British Salvarsan Committee.

The chief statistics available to the Salvarsan Committee have been those obtained from military hospitals, as, for various reasons, less reliance can be placed on the records of civil venereal clinics. As a result of its investigations the committee has arrived at the conclusion that no special arsenobenzol preparation must be regarded as more likely than another to produce ill effects. Moreover, when accidents have occurred errors in technique in administration have seldom been found to be responsible. There have been fatalities even under the most careful control, and in large and well-equipped hospitals.

The most important ill effects which may end fatally were found to be ocephalitis haemorrhagica, acute yellow atrophy of the liver, and exfoliative dermatitis and its complications. Encephalitis haemorrhagica usually occurs within two or three days after an injection, and most frequently after the second injection of the series. Disorders of the liver provide a very large number of the ill effects following arsenobenzol treatment, and may occur as an early jaundice or as a late and more dangerous lesion. The pathology of the latter lesion is still in some doubt, and it has even been suggested, especially in Germany, that it is not directly due to arsenobenzol. Skin reactions following salvarsan are fairly common, but fortunately they are light and transient as a rule, the only reaction or lesion of serious significance being exfoliative dermatitis. There exist certain other ill effects which may end fatally, but fortunately these are but rarely encountered; they include acute renal damage, ulcerative enteritis, polyneuritis, and aplastic anaemia.

Some of the ill effects which are recognized as being due to salvarsan may without hesitation be ascribed to the arsenic which it contains. The lesions capable of such explanation are gastritis, enteritis, and exfoliative dermatitis. The so-called "crises nitritoides," vasomotor phenomena, and liver lesions are, on the other hand, probably produced by arsenobenzol poisoning rather than by arsenic. An interesting point in connexion with the latter is the observation that cases of severe jaundice and liver atrophy appear to have occurred in the form of small outbreaks localized to one or another hospital, and restricted in time to a few months of its practice. This fact has led certain observers to suggest that these liver lesions are not directly due to poisoning but are caused by an intercurrent microbial infection of the liver. The committee does not, however, favour this view. Before stating its conclusions as to the relation of arsenobenzol compounds to the occurrence of jaundice and acute yellow atrophy of the liver, the committee has made an exhaustive study of the literature and the experimental work on the subject. A brief examination of this is sufficient to show that a great diversity of opinion still exists as to the pathology of the condition, many observers believing strongly that salvarsan is not responsible for the condition. It is, however, impossible to get over the fact that before salvarsan came into general use in the treatment of syphilis comparatively few cases of jaundice were encountered. It is difficult therefore to accept the view that the spirochaete rather than the salvarsan is responsible for the hepatic lesions. For the view that it may be produced by an infective cholangitis arising from the intestine there would

appear to be more foundation. This supposition relies for support on the bacteriological findings of Stuart Macdonald and Fraunkel, who claim to have found organisms in the hepatic tissues of fatal cases. It is obvious, however, that little reliance can be placed on bacteriological examinations carried out after death and unsupported by blood cultures made during life.

But quite apart from the results of morbid histology, evidence is gradually accumulating that a course of arsenobenzol treatment is followed in practically every instance by a certain degree of hepatic insufficiency, not enough to give rise to active symptoms, but capable of recognition by means of special tests. Such tests have been carried out at St. Bartholomew's Hospital by Dr. Mackenzie Wallis, and by Spence and Brett elsewhere. For this purpose two tests have been employed—namely, laevulose toleration tests and the estimation of the lipase or fat-splitting ferment normally present in the blood. The main results obtained so far by Mackenzie Wallis may be summarized as follows: (1) The effects of one or two injections of arsenobenzol preparations are almost always very slight, and little evidence of hepatic damage may be found at the end of a course of six injections. (2) The most striking results are obtained when the tests are applied three months after the last injection. Evidence of hepatic insufficiency is then detected almost invariably, although no clinical signs of hepatic disorder may be discovered. Six months after the last injection all evidence of hepatic insufficiency has gone, in cases where three months before it was clearly in evidence. It is obvious that the importance of these findings, if widely confirmed, may be very great in connexion with the safe spacing out of courses of arsenobenzol treatment.

Whilst recognizing the importance of exercising great care in the administration of "606" and "914," the committee is completely in accord in expressing the view that arsenobenzol preparations are more efficacious than any other drug yet available for the cure of syphilis:

"Although it is true that even this preparation cannot be guaranteed to effect an absolute cure, except in the early stages of the disease, it is now well established that a considerably larger proportion of cures can be effected by salvarsan and its allies than by any other form of treatment."

The committee's report ends with the following conclusions:

"It is believed that the very small number of unavoidable deaths due to this treatment are immeasurably outweighed by the deaths and disabilities which would arise if the older methods of treating syphilis were alone practised. At the same time the facts which have been brought together in this report no less strongly emphasize the importance of the most scrupulous care in the administration of a drug which is necessarily employed in doses not far removed from the danger line."

MINISTRY OF HEALTH: ANNUAL REPORT.

FIRST NOTICE.

THE third annual report of the Ministry of Health relating to the year ended March 31st* has been issued. It consists of 166 pages, and embraces a large amount of information not covered by Sir Alfred Mond in his speech on the vote.

In the prefatory note on the conditions of economy mention is made of the appointment by the Government of a committee of inquiry under the chairmanship of Lord Meston, to report what system of Exchequer grants for locally administered services can be substituted for the percentage grant system wholly or in part. This year—as already announced—the course adopted in order to keep down expenditure is to give grants of fixed amounts for most of the services instead of percentage grants. In reference to National Health Insurance additional benefits it is stated that over twelve million insured persons in England were affected. The cash benefits of nearly four millions of these had been increased, over four million became entitled to new services, and nearly four and a half millions became eligible for advantages of both these kinds. Nearly £150,000 a year may be devoted to dental treatment, and nearly £300,000 a year to payments to hospitals or convalescent homes on behalf of members of societies which have included these additional benefits in their schemes.

Tuberculosis.

The first section of the report treats of health administration in England, Great Yarmouth and the North Riding County

* Reports of the Salvarsan Committee. II. Toxic Effects following the Employment of Arsenobenzol Preparations. Special Report Series, No. 66. Stationery Office, 1922. Price 2s. net.

* Cmd. 1713. Price 6s. To be obtained from H.M. Stationery Office or through any bookseller.

Council having completed their scheme during the year, arrangements have now been made by all the county councils and county borough councils for dispensary and residential treatment of insured and uninsured persons suffering from tuberculosis. The number of dispensaries has been raised to 421, an increase of 10. The number of tuberculosis officers working under schemes of local authorities on March 31st was 339. The total number of institutions provided by local authorities and by voluntary arrangement was 433 and the number of beds 18,884, showing an increase of 1,492 beds. The number of additional beds which have been or are being provided under the term of the circular letter of November 3rd, 1919, will, under financial stringency, be limited to under 5,000.

The cost of residential treatment of ex-service men is borne by the Ministry of Pensions. The number receiving it on April 1st was 2,789, as against 3,559 on April 1st, 1921. The Public Health (Tuberculosis) Act, 1921, enables county and borough councils to arrange for the after-care of sufferers, and up to March 31st schemes of thirty-eight local authorities for setting up committees have been approved. In London interim committees were constituted in each borough during the war, and suggestions have now been given to them to organize permanent care committees to work in co-ordination with tuberculosis dispensaries. The matter of extra nourishment for persons under treatment for tuberculosis now evolves upon local authorities. The report says:

"It was not contemplated that extra nourishment should be provided by local authorities in other than limited classes of cases where the provision was likely to be of material assistance to treatment; or that more than limited expenditure should be incurred on this form of provision."

So far 119 local authorities have undertaken the provision on the lines of the circular letter of November 3rd, 1921. The expenditure of local authorities on this service ranking for Exchequer grants is limited to a maximum of £2 per annum per thousand of the population of the area of the authority.

Veneral Diseases.

The outstanding features in the campaign against venereal diseases in England during the year were a large diminution in the number of new patients attending the treatment centres and an increase in the total number of attendances of patients. The number of patients dealt with for the first time in 1922 was 79,000, as compared with 99,000 in the previous year. The number of attendances at treatment centres was 1,534,000, as compared with 1,434,000 in the previous year. The returns of the work done at treatment centres during 1921 show that, out of 52,000 cases which were accorded as having ceased to attend at the centres during the year, 13,000 were discharged after completion of treatment and subsequent observation, 14,500 ceased to attend after completion of one or more courses of treatment but before final tests as to cure, and 24,500 ceased to attend before completion of a course of treatment.

Maternity and Child Welfare.

The report states that the whole of England is now covered more or less completely by schemes for maternity and child welfare carried out by local authorities. It is part of the duty of the medical officer of health to supervise the scheme, but the executive medical work is generally carried out by the whole-time medical officers or by general practitioners. The department has, in the past, urged each authority to appoint an assistant medical officer, preferably a woman, with special aptitude and experience, to supervise the work under the direction of the medical officer of health. Ninety-three local authorities have one or more assistant medical officers for the purpose. The work of such an officer is not necessarily confined to maternity and child welfare, but is very often combined with other duties, such as the inspection of school children. The total number of women acting as health visitors on March 31st was 3,378. Of the 48,618 women on the Midwives Roll (covering the whole of England and Wales), 12,052 gave notice of the intention to practise as midwives in 1921. Eighty-two per cent. of the total on the roll are now certificated. In 1920, the last year for which figures are available, the percentage of births notified by midwives was 47.7 in London, 66.9 in the county boroughs, and 47.1 in the counties. Over 100 new district nursing associations were started in England during 1921, and only 12 of the existing associations ceased work. Of the rural population of England 71 per cent. is now provided with the services of a trained midwife. On a rough estimate with the more district nursing associations were needed to provide a complete service in rural districts, and it was hoped that as financial circumstances improved these associations would gradually be established, while others had authorized the medical officer of health to employ a nurse when necessary. Grant was payable in respect of the home nursing of maternity cases and for certain infectious diseases in young children,

such as measles, whooping-cough, epidemic diarrhoea, poliomyelitis, and ophthalmia neonatorum. About 140 local authorities had contracted with the local district nursing associations. The trustees of the Carnegie United Kingdom Trust gave £100,000 to provide model centres at a cost of £25,000 each in Liverpool, Birmingham, Shoreditch, and Rhondda. It was a condition that the local authority should maintain the centre, and the department was unable to make a definite promise of grant in aid of maintenance until the estimates of expenditure on this service had been examined. It has now been found that a margin of public money is available, and steps are being taken to establish these institutions.

Welfare of the Blind.

Under the Blind Persons Act, 1920, which came into operation on September 10th, 1920, those who had reached the age of 50 were entitled to pensions as they would have been under the Old Age Pensions Act if they had attained the age of 70. On March 31st, 1922, nine thousand one hundred and seven blind persons in England and Wales between the ages of 50 and 70 were in receipt of old-age pensions. From the date of the operation of the Act to March 31st, 1922, 3,267 appeals relating to claims were received. Of these, 1,423 were referred to the regional medical staff and 45 to ophthalmic specialists on the question of the degree of blindness. The two inspectors are carrying out investigations into the voluntary agencies and are assisting local authorities to prepare schemes. The advisory committee has made numerous recommendations to the department. The committee appointed to investigate and report on the causes of blindness expects to conclude its deliberations at an early date.

Other Services.

Other sections covered in the report under the heading "Public Health" include the inspection and supervision of food, sanitary administration, housing and town planning. The report deals also with local government and local finance, the administration of the Poor Law, old-age pensions, and National Health Insurance. To this last-named part we shall recur on another occasion.

Welsh Board of Health: Public Health.

In regard to tuberculosis treatment it is stated that in Wales all the councils act for this purpose through the Welsh National Memorial Association. The contributions which the County and County Borough Councils have agreed to pay to the Association amount in the aggregate to £68,442, approximately equal to a rate of 1.34d. This represents an increase of 0.34d. on the rate agreed for the previous year. The residential institutions of the Association on March 31st consisted of four sanatoriums with 600 beds, and 10 hospitals with 501 beds. Arrangements are also made for the treatment of patients in 14 institutions belonging to other authorities or bodies. The conversion of Craig-y-Nos Castle, Brecknockshire, into a hospital with 300 beds was nearing completion, and at Machynlleth, Montgomeryshire, with 30 beds, were also nearly completed. The Association had also offered a mansion midway between Cardiff and Newport for conversion into a hospital with 100 beds, and had been authorized to proceed with the scheme. Approval had also been given for the acquisition of property at St. Bride's, Pembrokehire, to provide accommodation for 100 children. When these hospitals were completed, two at Newport would cease to be used. There were now established in the principality 14 central dispensaries, round which were grouped 89 visiting stations.

IMPERIAL CANCER RESEARCH FUND.

The annual meeting of the Imperial Cancer Research Fund was held at the Examination Hall, Queen Square, Bloomsbury, on July 19th, with the Duke of Bedford, K.G., President, in the chair. Amongst those present were Sir William Church, Sir Humphry Rolleston, P.R.C.P., Sir Anthony Bowlby, P.R.C.S., Sir George Makins, Sir John Bland-Sutton, Dr. William Bulloch, Sir D'Arcy Power, Sir Charles Ballance, Sir Thomas Barlow, Sir Frederick Andrewes, Dr. J. A. Murray (Director), Dr. Russell, and Mr. F. G. Hallett (Secretary).

Sir WILLIAM CHURCH, in moving the adoption of the twentieth annual report of the Fund, sketched the principal researches which had been carried on, as stated in the Director's report published in full below. The motion was seconded by Sir JOHN BLAND-SUTTON and carried. The Duke of Bedford, in moving a vote of thanks to the executive and other committees and their staffs, said:

George Makins) for their services during the year, said that the income for the past year, including a legacy of £250 from the late Mr. William Crouch, has been the same within £5 as that of the previous year—in round numbers, £6,500. The treasurer, by careful economy, had been able to effect a reduction of £740 on the year's working, with the result that the excess of expenditure over income was only £12; but this sound finance has only been possible by lessening the activities of the Fund—a regrettable necessity. The financial future was brighter owing to two generous gifts for research work. The one from Lord Atholstan of £2,000 a year for ten years, which he desired should be devoted to special research; the line of this research has been decided upon by the Executive Committee on the recommendation of a special subcommittee. The other gift was one of £4,000, about to be presented to the Fund by Mr. and Mrs. Todman of Sydney, New South Wales, in memory of their daughter. Without these donations the Fund would have been compelled to have continued a policy of restricting the research work, or meeting an annual expenditure out of capital, both most undesirable. "In the early part of this year," the Duke of Bedford said, "there was a considerable correspondence in the press on the subject of cancer. All the letters, with I think one exception, showed an absence of knowledge of the facts, which have already been ascertained; indeed, it is remarkable that those who venture to address the public through the press on the subject of cancer do so without troubling to make themselves acquainted with the facts already determined. In this connexion it was thought advisable to send a letter to the *Times* on February 9th, setting out the various organizations engaged in cancer research in this country and abroad, together with a summary of the work already accomplished by our Fund." The Director's report, the Duke continued, showed that four different lines of research were being followed in the laboratories of the Fund, and it was hoped to initiate others. At present the real fundamental problems of the causation and prevention of cancer remain unsolved, and it was on these problems that the Fund was concentrating its resources. Meantime in the struggle against cancer it was of vital importance that the public mind should be impressed and seized with the enormous value of early diagnosis and treatment. Every effort therefore should be made to secure improvement in the early diagnosis of the disease. Precise methods of diagnosis involved knowledge of the mode of origin and nature of the disease, and the researches into these purely scientific aspects of the cancer problem have the greatest practical value. Thanks were due to Dr. Murray, the Director, and to Dr. Russell, Dr. Cramer, and Dr. Drew for their valuable work in carrying on the work of the Fund during the year.

Sir GEORGE MAKINS moved a resolution recommending the Royal Colleges of Physicians and Surgeons to reappoint Sir William Church and Sir Thomas Barlow, whose period of office had expired, as members of the Executive Committee; this was seconded by Sir CHARLES BALANCE and adopted. Dr. William Bulloch, F.R.S., was re-elected a member of the Executive Committee, and Professor A. E. Boycott, F.R.S., was elected a member in place of the late Sir G. Sims Woodhead. Sir HUMPHRY ROLLESTON proposed a vote of thanks to the Duke of Bedford for presiding; this was seconded by Sir THOMAS BARLOW and unanimously agreed to.

REPORT OF DIRECTOR.

Vitamins and Cancer.—In continuation of his studies on vitamin deficiency, Dr. Cramer, in collaboration with Dr. Drew, and with Dr. Mottram of the Radium Institute, has investigated the effects of vitamin A deficiency in rats. They have found that the most constant change is a progressive diminution in the number of the blood platelets. When the number falls below half the normal (which for the rat is roughly one million per cubic millimetre) certain symptoms develop. Although there is not necessarily any loss in weight if vitamin B is supplied, the animals develop infections (such as the xerophthalmia, so frequently noted in vitamin A deficiency), characterized by the presence of micro-organisms which are non-pathogenic to normally fed animals. These infections clear up with magical rapidity when the missing vitamin A is added to the diet—for example, as cod-liver oil. Parallel to this improvement the number of platelets returns to the normal and may rise above it. If the platelets for any reason do not increase in number, the general condition does not improve and the local infections do not regress. So constant has this relation been between platelet number and the condition of the animals that the authors regard their diminution as the specific lesion

of vitamin A deficiency, just as the diminution in lymphocytes measures the effects of vitamin B deficiency. The collaboration with Dr. Mottram has elicited a parallel between vitamin A deficiency and prolonged, repeated exposure to the gamma radiation of radium. Here, however, the concomitant effect on the number of lymphocytes necessitates careful spacing and dosage, to avoid the acute symptoms which accompany this blood change. When this is done a progressive diminution in the platelets is induced, accompanied by the symptoms characteristic of vitamin A deficiency. Dr. Mottram's studies, experimental and clinical, go to show that the aplastic anaemia of x-ray and radium workers is secondary to these changes in the lymphocytes and platelets, and is probably the consequence of similar infectious with relatively non-pathogenic organisms. Repeated attempts have been made to ascertain whether vitamin A deficiency has any influence on the growth of malignant tumours. Unfortunately it is difficult to keep animals alive for any length of time after a severe degree of this deficiency has been established. In the experiments carried out so far the tumours take in the same percentage as in the control animals and grow progressively, even when the rats are moribund. The enhanced liability to otherwise innocuous bacteria frequently ends these experiments prematurely, but the results give no encouragement to the idea that withholding vitamin A could usefully assist in the control of the growth of cancer in man. They emphasize the danger of the insidious debility which vitamin A deficiency induces. The progressive atrophy of the cells and organs forming lymphocytes and blood platelets respectively, which results from the absence of vitamins A and B in the food, and which causes ill health, is also produced by exposure to x-rays and radium. This is, in fact, one of the effects on the body as a whole which limit the degree of application of these rays in the treatment of new growths. If these blood changes develop, radiation must be interrupted and the patient allowed to recover. This recovery is materially assisted by an ample supply of vitamins in the diet, which stimulates the production of lymphocytes and platelets.

Culture of Tissues in vitro.—Dr. Drew has published an account of some of the work of the past two years on the culture of normal and malignant tissues *in vitro*. He has found, as have other workers, that for continuous growth outside the body all tissues require, in addition to the ordinary food substances, certain substances only available at present in fresh embryonic extracts. Extracts of adult tissues, and possibly tumours, contain this activating principle in much lower concentration. Its nature is still unknown; it is destroyed by heating, and it cannot be replaced by glutathione. We are indebted to Professor F. G. Hopkins for a supply of this dipeptide both in the reduced and the oxidized condition. Dr. Drew has been able to prepare a liquid medium in which tissues can be cultivated, thus eliminating the use of blood plasma, which has been a great hindrance to progress in this kind of work. Cell division and differentiation can proceed normally in this medium, the essential peculiarity of which is a definite colloidal condition of the calcium salts. Interesting observations have been made on the conditions which determine differentiation of normal and malignant cells. Epithelial cells when growing alone in pure culture remain undifferentiated. When connective tissue cells are added to such pure cultures, differentiation sets in with little delay, squamous epithelium producing keratin in the familiar form of concentric corpuscles, mammary epithelium producing acinous branching structures, even when originally derived from a practically undifferentiated alveolar mammary carcinoma. These experiments, which are only at their beginning, break new ground in the experimental control of the behaviour of metazoan cells. Intimately bound up with this problem is the curious fact that the continued culture *in vitro* of malignant cells encounters difficulties not met with in the experiments with normal tissues. If degenerative changes are to be prevented the former must be frequently transferred to fresh nutrient medium. The exhausted fluid is found to have a poisonous action on the tumour cells, but normal cells can grow, apparently without damage, in these fluids. These results give the greatest encouragement to the hope that by this method of experiment the fundamental differences between normal and malignant growth will finally be elucidated.

Respiration of Tissues, Normal and Malignant.—Dr. Russell has published an account of the continuation of his researches on respiration of normal and malignant tissues, in the period of survival after removal from the body. It may be as well to repeat that earlier experiments, mentioned in last year's annual report, showed that rapidly growing tumours, and certain normal tissues, notably kidney, showed such a gaseous exchange as indicated the consumption of carbohydrate, while slowly growing tumours gave respiratory quotients indicating

the combustion of fats. When, now, the emulsions of the latter group were made with solutions of glucose and certain other sugars, the respiratory quotient rose nearly to unity, showing that their parenchymata were able to oxidize these carbohydrates, if present in sufficient concentration. The attempt was made by subcutaneous injection of such sugar solutions, into animals bearing tumours, to find out whether in this way the rate of growth could be influenced. No alteration was produced.

Experimental Production of Cancer.—The experiments on the production of skin cancer by the external application of tar are being continued. They have resulted in the production of a large number of tumours, many exhibiting a high degree of malignancy, as evidenced by spontaneous lymphatic and blood-stream dissemination, but they have not advanced sufficiently far for publication, and nothing further need be said about them at present. Dr. Russell carried out an experiment on the effects of repeated inoculation of small quantities of coal tar in rats and mice. Two sarcomata were produced at the site of inoculation, one in a rat and one in a mouse, out of 50 mice and 40 rats inoculated. Autoplastic and homoplastic transplantation was successful with both these tumours, and metastases were found in the lungs of the primarily affected rat. An account of these experiments is in the press.

The recent correspondence in the lay press on cancer and cancer research exemplifies a distraction with which the worker on this subject has to contend. None of the more or less distinguished writers of the letters, with the exception of H.E. the Aga Khan, displayed any acquaintance with the results of the work of the last twenty years. The facts already known as to the occurrence of cancer in different races of mankind, and in different species of animals, published in the first, second, and third scientific reports of this Fund were treated as non-existent.

FINANCIAL POSITION OF HOSPITALS.

CONFERENCE OF LOCAL VOLUNTARY HOSPITAL COMMITTEES.

A NATIONAL conference of representatives of local hospital committees, arranged by the Voluntary Hospitals Commission, of which the Earl of Onslow is Chairman, has been held at the Ministry of Health. Representatives were present from every one of the committees now functioning in England and Wales, as well as a number of representatives from Scotland. Viscount Cave was in attendance at both sessions, as well as Lord Clwyd, Lord Somerleyton, Sir George Makins, Dr. R. A. Bolam (representing the British Medical Association on the Commission), and Captain W. E. Elliot, M.P.

Lord Onslow, in opening the proceedings, said that the policy of the Government was to maintain intact the voluntary hospital system. The first duty of the Commission was to administer the grant made by Parliament to meet the immediate needs of the hospitals, and the administration made local machinery necessary. Such machinery already existed in London in the shape of King Edward's Hospital Fund; elsewhere committees had to be set up, and there were now 54 such bodies and only eight areas in which committees were not functioning. It had been anticipated, largely on the basis of the figures for 1920, that the hospitals' deficit for 1921 would be £1,000,000, and the grant was intended to cover half that deficit. The Commission had decided that, subject to some final adjustment when all areas had sent in their claims, the sum of £225,000 should be allocated to London, and £275,000 to the rest of the country. It appeared, however, that the deficit might be only £750,000, and in that case a sum of £125,000 out of the £500,000 grant would remain to be allocated after half the 1921 deficiency had been met. The distribution of this residue would have the anxious attention of the Commission. All the information before the Commission tended to show that the cost of maintenance was declining and that the income was certainly being maintained, and in many cases increased.

A Standing Consultative Committee.

The first matter dealt with by the Conference, on the initiative of the Manchester Committee, was a proposal for the setting up of a standing consultative committee to represent all the local areas as far as possible, and to act as a liaison between the Commission in London and the local bodies. Dr. C. E. S. FLEMING was anxious that every type of hospital, from the teaching institutions to the cottage hospitals, should be represented; and Sir ARTHUR MAY that representatives of the less populous areas should be included. This last suggestion was adopted as a rider to the main proposal, which was agreed to unanimously, and it was under-

stood that this consultative committee, to consist of some twelve or fifteen persons, would be appointed in the first instance by the Commission itself.

Local Committee Administration.

Mr. H. N. CROUCH (Somerset) said that the committee areas should be regrouped; it was not desirable that city hospitals should be worked independently of country hospitals. A resolution that each area should be so arranged as to constitute a suitable unit for bringing about better co-ordination between existing hospitals was tacitly agreed to, and was referred to the local committees for their observations.

On a question raised at the instance of the North Wales Committee as to payment of administration expenses of local committees, Lord CAVE said that the committee over which he had presided had difficulty in recommending that the voluntary committees should have the right to payment of expenses from county or other public funds, but he thought the matter capable of amicable adjustment with the local authority in each area, and said that his own county council (Surrey) had provided a bank balance for the committee.

Hospital Extension.

It was agreed, on the motion of Lord ONSLOW:

That local hospital committees should not recommend any extension scheme to the public unless they are satisfied:

(a) That the extension is necessary and is planned on a reasonable scale and that the services cannot be provided by co-operation with other institutions;

(b) That sufficient funds will be available within a reasonable time for the execution of the scheme or an effective part of it; and

(c) That funds are or will be available to meet the cost of maintenance of the hospital, including any additional maintenance charges resulting from the extension, and that the appeal for capital expenditure will not prejudice the raising of the funds required for the maintenance of the hospital itself or other institutions in the area.

Administration of Government Grant.

A long discussion took place on the administration of the Government grant. The Devonshire Committee proposed that the average deficiency over a period of three years should be adopted as the basis of distribution instead of the deficiency in 1921, and the Manchester Committee that accumulated deficits should be taken into account in fixing grants. Mr. H. R. MAYNARD (secretary of the King Edward's Hospital Fund) said that in the case of any residue his Fund had given preference to cases in which the accumulated deficits had been such as to exhaust the borrowing powers of the hospital. A hospital might not be gravely hampered by a temporary deficit even if it extended over two or three years; the whole situation of the hospital must be considered. Lord CAVE agreed that any balance of the Government grant remaining after the deficit for 1921 had been met should be applied to the reduction of the accumulated deficits of previous years. Lord ONSLOW believed that the residue must be distributed on the basis of the accumulated deficits previous to 1921, but the distribution would in any case be difficult, and would probably give rise to criticism.

Workpeople's Contributions.

Mr. WALTER DAIN (Manchester) drew attention to the need for systematic collection from employers and workpeople. He suggested that the Commission should approach the Federation of British Industries and obtain the support of the trade union leaders also. Mr. F. M. OSBORN (Sheffield) gave particulars of the joint hospital council, embracing several hospitals in Sheffield, which in 1921 launched a scheme for workmen's contributions: the appeal to each workman was to set aside 3s. a week for the hospitals, and to the employers to add one-third to the workmen's contribution. Under this scheme last year £21,000 was received, and it was estimated that in 1922 the amount would be £28,000. There were 120,000 contributors; they had the right to treatment at a hospital on the presentation of a letter: non-contributors, other than the necessitous poor and children, were interviewed by lady almoners and asked to pay for their hospital treatment according to their means. Contributors were represented on the hospital boards and on the joint council. Unfortunately, municipal corporations were prevented from making the employer's contribution, and he hoped that this restriction would be removed. A representative from Chesterfield said that a scheme of contribution for employers and employees had been in operation there for twenty years. The workpeople subscribed at the rate of 2d. a week, the employers generally added one-third, and during last year £12,000, or 60 per cent. of the hospital income, was raised by this means. The Norfolk representative said that in his county 80,000 people had contributed to a scheme, which had a paid organizer and was worked through the Hospital Saturday Fund.

Approved Societies.

Sir WALTER KINNEAR (Controller, Insurance Department, Ministry of Health) described the efforts which had been made to interest the 9,000 approved societies. Unfortunately, the issue of the valuations report synchronized with a period of high cost of living, and the majority of the societies decided to devote their surpluses to increasing the sickness benefit under the Insurance Act. Nearly a thousand societies and branches, however, had been persuaded to devote a portion of their surplus to hospital provision, and schemes had been approved for the next five years, which should bring in £200,000 a year. The scheme, however, was not working well, owing to certain technical difficulties which he described, and up to the present only about £30,000 had been paid out. The difficulty arose over the arrangements for members of the societies to get treatment.

Other Methods of Raising Revenue.

The Birmingham Committee drew attention to the need for collecting contributions from areas not possessing facilities for hospital treatment. The question of payments by patients was on the agenda, but was barely introduced, owing to shortness of time. No resolution was taken on these matters, but it was agreed that the Commission should issue a set of questions to all committees as to the methods of collecting contributions and publish the results.

Co-ordination of Hospitals in Areas.

Lord CAVE, at the close of the Conference, said that although the first function of the local hospital committees had come to an end, he hoped they would remain in being to bring about the co-ordination of hospitals in the different areas. It was wasteful to have two great hospitals close together, and also to have hospitals in the same area equipped alike. He looked forward to a scheme, somewhat on the lines of Lord Dawson's report, in which there would be considerable mobility in the transfer of patients from one kind of hospital to another, as required. The committees had an important part to play in organizing or inspiring the collection of funds. Another duty which might be thrust upon them was the regularization of the system of keeping hospital accounts. He hoped that the Commission also would remain in existence. It might be that in time it would be superseded by some body wholly unconnected with the Government, but for the present it was very desirable that it should be under the Government aegis.

POOR LAW MEDICAL OFFICERS' ASSOCIATION.

The annual meeting of the Poor Law Medical Officers' Association was held at the offices of the British Medical Association, London, on Thursday, July 13th. At the opening proceedings, Dr. A. E. CORE (Chairman of Council) presided. Sir Arthur Newsholme was elected President in succession to the late Surgeon General Sir George Ewart. The annual report and balance sheet were approved and adopted. There being no other nominations the officers and Council of the Association were re-elected for the ensuing year.

Sir ARTHUR NEWSHOLME, the newly elected President, was heartily welcomed, and gave from the chair an interesting address. He paid a high tribute to the memory of the late President, referring to Sir George Ewart's persistent optimism and his longing to benefit his fellows. His fervent desire had been to do good and scatter the forces of evil and of disease.

The history of medical attendance on the poor in this country was regarded by Sir Arthur Newsholme as tantamount to the history of civilization. No one test of our distance from barbarism equalled that furnished by the care of the sick poor. Passing in review this progress from barbarism, he traced the history of the Poor Law service from feudal times to the present day. The Act of Richard II, in 1383, contained the beginnings of the principle of "settlement" which had been so mischievous in preventing the mobility of labour. During the reign of Charles II in 1662 this Act was renewed and extended. It made labourers cling to their parish under conditions allied to slavery, and caused untold injustice, fraud, ill will, and endless litigation, which had extended even up to the present time. Prior to the reign of Henry VIII the wanderings of vagrants had been controlled by terribly severe enactments. The drastic punishments, when no relief agencies existed, were found to provide no remedy. About this time a distinction was drawn between the sick and impotent who were unable to work and the lusty unemployed who could work. In the reign of Queen Elizabeth power was given to the magistrates to levy a tax on voluntary defaulters. The Church was utilized for this task, and thus in the earlier

days going to the "parish" had an ecclesiastical rather than a modern Poor Law significance. Overseers were appointed to provide for the impotent and to provide work in exchange for relief. Thus the coupling of work with relief became firmly established. It was towards the end of the seventeenth century that the institution of workhouses led to a great reduction in the claims on the poor rate. By Gilbert's Act (in 1782) the management of poor relief was no longer to remain entirely in the hands of overseers and churchwardens. The administration of the funds was entrusted to the magistrates, who were to appoint visitors and guardians, the latter being paid officials with duties like those of the modern relieving officer. This altered the fundamental principle of the workhouse. In 1796 outdoor relief to the able-bodied was specifically legalized. Following this and similar change the cost of relief bonused up. In 1834 the public funds were regarded as a regular part of the maintenance of agricultural labourers. These funds were administered in an absolutely uncontrolled manner. Then came the Royal Commission of the Poor Law in 1834, which concluded that the abuses and evils of the existing system were the direct result of indiscriminate outdoor relief to the able-bodied, and the conclusion was laid down that the pauper's economic situation or the whole shall not be made really or apparently so eligible as the situation of the independent labourer of the lower classes.

Then followed the formation of larger Poor Law unions and a rapid reduction of outdoor relief for the able-bodied. Sir Arthur Newsholme showed by statistics that the problem became one of old age, and when not old age it was sickness largely. Nursing by paupers had been prohibited in 1895. So rapid had been the organization of medical treatment that at this time there were twice as many beds in Metropolitan Poor Law infirmaries as in the voluntary hospitals, and nearly as many as in all the voluntary hospitals throughout England and Wales. The improvement in the quality of medical attendance and nursing in the best infirmaries had been no less remarkable. He considered it was only possible to solve satisfactorily the general hospital problem by securing more complete co-ordination of the work of the voluntary and special hospitals, thus relieving voluntary hospitals of a large number of chronic and incurable cases. Deterrent administration was legitimate for the able-bodied; though investigation of causes and conditions would often supply a more rational line of action, but for the actually sick the best which medical knowledge and devoted nursing could supply must be given. However the illness had been acquired, it was imperative, not only in the interest of the patient but also to secure the welfare of the community, that treatment should be prompt and adequate, and that no partial definition of what constituted medical treatment should be tolerated. To realize the full utility of Poor Law work it must be linked up with public health work by the closest bonds.

Quoting from his own last annual report as Medical Officer of the Local Government Board (1917-18), Sir Arthur said that Poor Law medical officers visiting the homes of the very poor, and familiar with their home conditions, became part-time Medical Officers of Health. But the attempt to combine prevention and treatment proved unsuccessful because the Poor Law medical officers visited only a small proportion of the dwellings of the poor, because they were not trained in preventive work, and because the good seed of preventive work was choked by the increasing competition of private medical practice. Ere long it should become practicable under more favourable conditions for medical practitioners engaged in clinical work, partially or entirely at the public expense, to be on the staff of the local public health authority in the district covered by their practice while carrying on their clinical work, to the great advantage of patients and of the public, as well as of the medical practitioners themselves. This would need to be organized in connexion with a general service, curative as well as medical. Its realization, though difficult, presents no insuperable difficulties.

Concluding his address the President considered that whatever changes were made the work and appointment of district medical officers must remain. Their present pay was inadequate. In the past they had been definitely exploited. Medical men had been found willing to undertake the work for insufficient pay so as to prevent the intrusion of rival practitioners. The preventive aspects of their work had not been sufficiently developed. Their relation to the institutional treatment of their patients had been unsatisfactory. The pressure in favour of reform would increase, and he looked forward to the time when their work would receive the acknowledgement, both socially and financially, which its national importance demanded.

Dr. ARTHUR DUNN proposed a hearty vote of thanks to the President for his inspiring address. This was seconded by Dr. RIDLEY BAILEY, supported by Dr. A. E. CORE, and enthusiastically carried.

Scotland.

VISIT OF FRENCH MEDICAL MEN TO EDINBURGH.

DURING the week ending July 22nd Edinburgh was visited by the Dean of the Faculty of Medicine of Paris (Professor Roger) and by the obstetric physicians who in 1921, and again in the present year, gave instruction in midwifery to the men and women students from Edinburgh who went to Paris. These teachers were Professor Paul Bar and Dr. Convelaire, who taught the men students, and Dr. Brindeau, who cared for the instruction of the women. Reference was made in the *JOURNAL* (March 12th, 1921, p. 400) to the work in Paris at the Clinique Tarnier and at l'Hôpital de la Pitié, in which the men and women respectively were accommodated. Dr. Trelat of Lyons also formed one of the party visiting Edinburgh, and there were some four or five French undergraduates. Professor Lorrain Smith, Professor Alexis Thomson, and Drs. Haig Ferguson, Lamond Lackie, Arthur Sinclair, and Oliphant Nicholson acted as hosts. On Tuesday, July 18th, the French guests were shown over the University, the Royal Infirmary, and the Royal Maternity Hospital. At the last-named institution they were received by Drs. Haig Ferguson and Lamond Lackie, and a photograph of the party was obtained in the garden behind the Ante-natal Department. Various entertainments and excursions had been arranged for the following days, and these were all carried out comfortably, the weather remaining fine during the whole of the visit. On Friday Professor Roger received the honorary degree of LL.D. from the University of Edinburgh.

DINNER OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

The annual dinner of the Medico-Psychological Association of Great Britain and Ireland was held on the evening of Wednesday, July 19th, 1922, in the Hall of the Royal College of Physicians, Edinburgh, with the President of the Association, Professor George M. Robertson, in the chair. The guests included Lord Provost Hutchison, Principal Ewing, Professor Lorrain Smith, Dr. C. Hubert Bond, Professor E. W. White, Sir George Paul, Sir Arthur Rose, Sir Robert Armstrong Jones, Sir Robert Philip, Sir David Wallace, Dr. J. A. Soutar, Mr. J. G. Jameson, M.P., Sir John Findlay, Sir Frederick Mott, Professor Alexis Thomson, and others. After the loyal toasts, Dr. J. A. Soutar proposed the toast of "The City of Edinburgh." He spoke of the warm affection in which Edinburgh was held by all who had enjoyed its citizenship and their pride not only in the beauty of the city itself but also in its glorious past. Lord Provost Hutchison, in replying, said that the fame of the city was in great part due to its medical and surgical school; as the science of psychiatry became better known he felt sure that Edinburgh would take a foremost place in this branch of medicine also. He felt that the city was peculiarly honoured not only in having as their guests the members of the Medico-Psychological Association this year but also in the election to the presidential chair of Professor Robertson. He also cordially welcomed to Edinburgh the distinguished French physicians now on a visit to the city. Dr. C. Hubert Bond, in proposing the toast of the University of Edinburgh, spoke of the affection in which the Alma Mater was held by all alumni. Edinburgh had not only instituted a chair of psychiatry but by arrangement with the managers of the Royal Edinburgh Hospital at Morningside the post of Professor of Psychiatry and superintendent of that hospital were one, and the election was vested in the two bodies. The city and university were alike fortunate in having Professor Robertson as the first holder of this chair. Principal Sir Alfred Ewing, in reply, emphasized the imperial character of the university, drawing its students as it did from all parts of the empire and sending them forth with the torch of learning to diffuse knowledge to the ends of the earth. More and more the world was looking to the universities as its guide, and if civilization were to be rescued from the slough in which it found itself it would largely be due to the influence of the universities. The speaker emphasized the educational value of the chair of psychiatry, and the satisfaction the university felt in that the chair was filled by a man of such intellect and breadth of vision as Professor Robertson. In conclusion he welcomed as honoured guests the Dean of the Faculty of Medicine in the University of Paris and his colleagues. Mr. J. G. Jameson, M.P., in proposing the toast of the General Board of Control, referred to the good feeling which existed between

the Board of Control and the local authorities. Sir R. Armstrong Jones and Sir Arthur Rose, D.S.O., replied. The toast of the Medico-Psychological Association was proposed by Sir R. W. Philip, who referred to the great advances and improvements in the asylum system and the altered point of view with regard to the mentally defective; he was now treated as a sick man whom we were out to help. As President of the Royal College of Physicians he welcomed the association to their hall, in which hung the portraits of Professor Laycock, Sir John Batty Tuke, and Sir Thomas Clouston. He congratulated the association on their choice of President. The Chairman, in replying, commented on the work that had been done by the association in the training of mental nurses in the duties of the profession. He also referred to the presence of representatives of France as the honoured guests of the association, and called on the company to join with him in honouring the toast of France.

TYPHUS AT RAASAY.

An outbreak of typhus on the island of Raasay was reported to the Scottish Board of Health last week. Although under the Highlands and Islands Medical Services scheme the island is under the supervision of Dr. Morison, Portree, the parish medical officer, there is no doctor resident on the island. On the occurrence of the outbreak the District Committee represented to the Board the desirability of arranging for the temporary appointment of a medical officer who would reside on the island to cope with the outbreak, and through the courtesy of the Midlothian and Peebles District Board of Control and of Dr. J. H. C. Orr, superintendent of the Rosshlynco Asylum, the Board were able to obtain the services of Dr. Francis Sutherland, M.B., Ch.B., D.P.H.

Correspondence.

THE PROCESS WHICH RESULTS IN AURICULAR FIBRILLATION.

SIR,—Sir James Mackenzie's article (July 15th, p. 71) is suggestive. May I draw the attention of your readers to the fact that the disparity between Sir James's conclusions and the theory of the circus movement is fundamental, each excluding the other?

Before I proceed further I should like to make one or two points clear in regard to the theory of the circus movement. We may readily admit that a serious attempt has been made by means of experiments to prove that the mechanism underlying fibrillation is a simple circus movement along one of the venous orifices of the right auricle. However, the conclusions arrived at by Sir Thomas Lewis and his co-workers in regard to the nature of the mechanism underlying fibrillation as expounded in the Oliver-Sharpoy lectures and in *The Heart* are not based on experiments at all. They are based on a gratuitous assumption for which no attempt whatsoever was made to produce a shred of evidence.

Unlike some of the predecessors of Sir Thomas Lewis who adopted the circus movement theory, he assumed that the cause which gave rise to fibrillation disappears with the onset of the abnormal rhythm. The cause of the continuation of fibrillation is the circus movement itself, and there is no relation whatsoever between the pathological condition of the heart and the abnormal rhythm. The auricle continues fibrillating for years just because once the circus movement started there is nothing to interrupt its course. While the auricle is in a condition of fibrillation it is perfectly normal. Accordingly, all that is necessary in order to restore the normal rhythm is to interrupt the circus movement. It was thus a gratuitous assumption which led to the amazing conclusions and not experiments.

It is obvious that if fibrillation is due to loss of control of a "higher agency," as Sir James maintains, the cause which originally gave rise to fibrillation remains potent even after the onset of the abnormal rhythm. What use would there be in attempting to interrupt the circus movement in order to abolish fibrillation, as recommended by Sir Thomas, if the cause still remains? The moment the circus is interrupted it would be restored again. This is also evidently the opinion of Sir James, who knew my criticism of the circus theory.

Clearly the circus movement theory as expounded by Sir Thomas Lewis becomes untenable once an attempt is made to explain auricular fibrillation on lines similar to those of other pathological phenomena.—I am, etc.,

Liverpool, July 17th.

I. HARRIS.

SIR,—After reading Sir James Mackenzie's article (July 15th, p. 71) I venture to think that as regards fibrillation in striated muscle a personal observation may be of interest.

Last summer, whilst working all day at the Liverpool Heart Clinic, I found myself getting out of condition through want of exercise and was frequently troubled with cramp in the lower extremities at night. To obviate this I went in for physical jerks of a morning in the bathroom, and in doing one of the exercises too energetically believe I ruptured some of the fibres of the left soleus, which caused me to be lame for about a fortnight and increased the frequency of the attacks of cramp in that calf.

Early one morning, after an unusually severe attack in which no sooner had I managed by manipulation to ease one spasm than some accidental movement would bring on another, I was sitting cross-legged on the outside of the bed idly staring at the leg, hoping that the disturbance was at an end, when a flickering of the skin over the affected parts, on which the sun was shining, attracted my attention. After putting on my spectacles I found that the flickering of the skin was limited to an area along the inner border of the tibia in its upper half about one inch by three inches. The flickering was rapid and of variable extent, sometimes just a little dimple, then a dimple and a short flash, then a multitude of flashes of all lengths. It waxed and waned like a display of aurora borealis, but I could make out no periodicity. After a time I shifted round so as to get the sun on the right leg. Here the corresponding area was quiet, but on flicking the posterior border of the tibia sharply with my middle finger-nail and thumb I managed to set up a similar display, but not so marked as in the injured leg. The above description is merely from recollection, as I cannot lay my hands on my original notes. I may say that I have occasionally seen a similar display over about the sixth and seventh left intercostal spaces in cases of effort syndrome in whom counting the ribs causes little flash-like horizontal ridges to appear along the left border of the sternum.—I am, etc.,

Manchester, July 22nd.

FRANCIS HEATHERLEY.

THE NATURE AND SIGNIFICANCE OF HEART SYMPTOMS.

SIR,—Sir James Mackenzie, in the BRITISH MEDICAL JOURNAL of July 15th, in response to Dr. Strachan's letter of July 1st, says: "He is quite right, and I shall take his suggestion, and use the word 'power' in place of 'force' in future." It is not clear to me that Dr. Strachan is quite right, or that Sir James will do well to use the word "power" in place of "force" in future. "Reserve force" and "rest, force" would then read "reserve power" and "rest power." I can understand what *reserve energy* or *potential energy* is, but "reserve power," and especially "rest power," have no apparent meaning.

The definitions of these terms are as follows:

"Force is that which produces (if unopposed) or tends to produce (if opposed) motion in matter."

"Energy is the capacity for doing work." It is measured by the amount of work done or doable.

"Power is the rate at which work can be done." Power, if uniform, is the amount of energy transformed divided by the time required for the transformation. The horse-power of an engine, or of the heart, depends on the amount of work it can do in a unit of time—that is, its rate of working.

Energy corresponds to capital, and power to rate of expenditure. As applied to the heart the term "force" would be used to express the effort of the heart to work, "energy" the amount of work the heart does or can do, and "power" the rate at which it does it.

When in 1911 Dr. Mackenzie said, "The rest force is the minimal force which the heart can exert to maintain the circulation at a level consistent with life," I pointed out that he should have said, "It is the minimal *energy* which the heart can expend to maintain the circulation at a level consistent with life." The word "power" might have done there as expressing the minimal work done at the minimal rate, but the term "energy" seems more clear and precise.

All three terms have their uses and values, and I hope that Sir James Mackenzie will not adopt "power" and exclude "force" and "energy," but be impartial in the use of all as occasion demands.—I am, etc.,

Clyst St. George, Devon, July 18th.

D. W. SANWAYS.

BUBONIC PLAGUE TREATED WITH NEO-SALVARSAN.

SIR,—In a memorandum on bubonic plague treated with neo-salvarsan, in your issue of July 22nd, Dr. Ram Mansoor states that "prophylactic treatment by vaccines confers immunity for a very limited period, and even then the results are not very encouraging. Some years ago, in a small village in the Punjab, inhabitants were inoculated with vaccine, but unfortunately more than three-fourths died."

A statement of this kind is apt to do an immense deal of harm, because anyone reading it who has not had experience of the great value of Haffkine's prophylactic in outbreaks of plague would likely conclude that the inoculations are not only useless but also dangerous. Dr. Ram Mansoor does not mention that the Mui Kowal tragedy happened twenty years ago, and was due not to the prophylactic prepared in the laboratory, but to an accident that occurred to the contents of one of the bottles just before use by which one bottle out of a brew of five became contaminated with earth and the tetanus bacillus. The circumstances attending this accident were that the assistant, when removing the cork of one of the bottles, let the forceps he was using for that purpose fall to the ground, and instead of immediately sterilizing by heat, as should have been done in the flame of the lamp before further use, he simply dipped the forceps for a moment in a solution of carbolic acid, and then proceeded to withdraw the cork, contaminating the contents of the bottle with the drippings from the soiled forceps.

As regards the period of immunity conferred by inoculation with Haffkine's plague prophylactic, it is longer than that conferred by either typhoid or cholera inoculations, while the results, instead of being, as Dr. Ram Mansoor asserts, "not very encouraging," are on the contrary very good and of much service, the average reduction amounting to three times fewer attacks among the inoculated, and should the inoculated take plague the chances of death are reduced at least twice. Accordingly, the chances of escape from death are six to one in favour of the inoculated, and in many cases they have been more than ten to one in favour of the inoculated.

For populations exposed to infection of bubonic plague and living under crowded and insanitary conditions my experience is that inoculation with Haffkine's prophylactic is one of the quickest and most powerful weapons we at present possess in preventing the spread of an outbreak of plague, and that it is quite harmless provided proper precautions are taken in its application.—I am, etc.,

London, N.W., July 24th.

W. J. SIMPSON, M.D.

TENDON TRANSPLANTATION.

SIR,—In a clinical lecture on tendon transplantation, published in your issue of July 15th, Mr. Ollerenshaw refers to a statement made by me in a lecture published in the BRITISH MEDICAL JOURNAL of April 9th, 1921. The statement was to the effect that, though open to conviction, I had not at that time seen a transplanted "biceps contract alone at will and produce extension of the knee-joint."

I feel it is incumbent upon me to admit that since writing those words I have been convinced that such a movement can take place as the result of voluntary contraction of transplanted hamstrings. Early this year, at a meeting of the Orthopaedic Section of the Royal Society of Medicine, Dr. Pugh showed a case of poliomyelitis in which Mr. Trethowan had transplanted the biceps and, I think, the semitendinosus into the patella. In this case extension of the knee was undoubtedly produced by voluntary contraction of the transplanted muscles. The fact that some who saw the case thought they could feel evidence of slight return of power in one of the quadriceps muscles did not in the least disturb the general conviction that the movement was produced by the biceps and semitendinosus and not by the quadriceps. I still think that in the cases in which this operation is followed by an apparently successful result the quadriceps has almost invariably recovered some of its power unexpectedly.—I am, etc.,

London, W., July 21th.

H. A. T. FAIRBANK.

THE PROTECTION OF RADIOLOGISTS.

SIR,—It is remarkable that, in the preliminary report of the X-ray and Radium Protection Committee, no warning has been given of the danger from unprotected valve tubes.

X-rays are emitted from nearly all valve tubes as they

July 8th.

A. C. NORMAN,
Director, Fray Institute of Iraq, Baghdad.

THE TEACHING OF PSYCHOTHERAPY.

THE TEACHING OF PSYCHOTHERAPY.

Sin,—In the course of your admirable article entitled "What is a consultant?" you take occasion to reprove those of us who practise psychotherapy for accepting patients other than those who have been introduced by a general practitioner. Our reply to this is that "We must live," even though by that statement we lay ourselves open to the retort on the part of some at least of our medical brethren, "We do not see the necessity." The psychotherapist is in a peculiar position which marks him out from the consultant in general, and that is that he is not called upon to advise, but to treat. If he consider the case a suitable one for his specialty, he must of necessity replace the family practitioner and take over the case entirely himself. It is therefore only natural that the general practitioner, who is most probably himself somewhat distrustful of psychic methods, should hesitate before passing on his patient. It would be better, from the point of view of both the patient and the practitioner, if the specialty were looked at from the point of view of a surgical operation. The practitioner

The practitioner does not complain that the surgeon he takes the case out of his hands and applies the treatment himself; nor does the patient complain of the long valescence and the large fees which he has to pay. These things are looked upon as inevitable. It is far otherwise at present with psychotherapy. The public are in no matter somewhat ahead of the medical profession, and see it out, albeit shamefacedly. But were they backed up by the confident recommendation of the family physician or the would be easier and more satisfactory. As matters stand we are either looked upon as quacks or expected to perform miracles of healing in the space of a week or so. The remedy obviously lies in the education of the profession in the use and usefulness of psychotherapy. This can only be done through the medium of the medical schools and hospitals. As far as I am aware there is at present no medical school which gives any space to psychotherapy in its curriculum. No doubt this is partly due to the idea that the science is still in a state of flux, and that it cannot be taught until a more stable condition has been reached. This is a misconception, as examination of the teachings of the pioneers Freud, Jung, and Adler would show that the differences between the rival schools are those of technique rather than fundamental. The fact that so many of our leading neurologists now give full recognition to the value of psychotherapeutic method proves that the groundwork of the new movement is sufficiently firmly based to make it possible to teach it to students. A further difficulty is the lack of a suitable text-book.

A further difficulty is this. Supposing the student to have had his interest in psychology and functional nervous disorders quickened and stimulated by a course of lectures, how is he to acquire the necessary technique? The nature of the psycho-analytic method makes it impossible to treat cases before a crowd of students, or, indeed, in the presence of anyone except the analyst. This difficulty will always remain, but although students cannot therefore be shown the science in working, it should be possible to exercise them in the interpretation of dreams, and if only some half-dozen keen spirits were to work systematically at the interpretation of their own dreams under the guidance of the lecturer their combined researches might shed light on many of the problems of dreaming which are still obscure. I do not suggest that any freshly qualified student should at once apply himself to the practice of psychotherapy as a speciality, however keen his interest may be. Experience in the treatment of general diseases, some knowledge of the world, and above all a thorough insight into his own personal problems are indispensable for the psychological physician. These things can only be acquired with time; but whether or no the student eventually takes up the speciality whole-heartedly his psychological training will stand him in good stead both in his professional and private life, and will not be the least part of the equipment which makes for success.—I am, etc.,

R. MACDONALD LADELL.

Birmingham, July 18th.

R. MACDONALD LADELL.

Universities and Colleges.

At a congregation held on July 19th the following medical degrees were conferred:

M.D.—O. Heath,	UNIVERSITY OF CAMBRIDGE.
M.B., B.Ch.—T. L. Hillier, H. Spibey	
M.B., B.Ch.—E. H. Oakeley, C.	
B.Ch.—A. A. Goss,	

M.D.—O. Heath.
 M.B., B.Ch.—T. L. Hillier, H. Spibey.
 M.B.—H. E. H. Oakeley, C. B. Clarke.
 B.Ch.—A. A. Gentwall, A. G. P. McArthur, C. J. Feuny, B. Mountain.

UNIVERSITY OF EDINBURGH.
ceremony on July 21st the hon
ferred upon four
K. R. F.

UNIVERSITY OF EDINBURGH.

At the degree ceremony on July 21st the honorary degree of Doctor of Laws was conferred upon fourteen persons, including Sir Isaac Bayley Balfour, K.B.E., M.D., F.R.S., Professor Emeritus of Botany in the University; Sir J. Halliday Croom, M.D., F.R.C.S., F.R.C.P., Professor Emeritus of Midwifery in the University; Bretnald Farmer, D.Sc., F.R.S., Professor of Botany and Director of the Biological Laboratories, Imperial College of Science and Technology, London; Professor H. Roger, Dean of the Faculty of Medicine of the University of Paris; Sir Charles Scott Sherrington, G.B.E., M.D., LL.D., F.R.S., Professor of the Faculty of the University of Oxford, President of the Royal Society; and John Thomson, M.D., F.R.C.P.E., Consulting Physician to the Royal Edinburgh Hospital for Sick Children, and John Leeturer on the Diseases of Children.

The Senatus recently offered to confer the same degree upon Mr. J. Garton, who had accepted it, but died before he could be presented. Mr. Garton first showed that the common grain crop and many other plants are self-fertilizing; he also invented the process of multiple cross-fertilization of crop plants and produced hundreds of new and improved varieties, which greatly increased the yields of all the common crops of the farm. Twenty-two years ago Mr. Garton provided the means to establish the Garton lectures on Colonial and Indian agriculture, and subsequently permanently endowed them as an integral part of the work of the chair of agriculture.

The following degrees were also conferred:

M.D.—J. Anderson, Rachel M. B. Benseau, H. C. D. Croft, G. G. S.

Following degrees were also conferred:

Fellowships and Prizes.

The following fellowships presented:

Thesis Gold Medallists: James Elvins McCarty, M.D., and Walter Quarry Wood, M.D., Ch.M. The Cameron Prize, M.D., and Walter Penrice, Frederick Cowland Hopkins, M.A. M.B., D.Sc., F.R.S., Professor of Bio-Chemistry in the University of Cambridge. The Syme Surgical Fellowship Norman M Omish Dott, M.B., Ch.B. The Gunning Victoria Jubilee Prize in Pathology: James Elvins McCarty, M.D., Ch.B., Ch.B. The Ellice

Medal: Joseph Owen Kelly, M.B., Ch.B. The Allan Fellowship in Clinical Medicine and Clinical Surgery: Bruce Mackenzie Dick, M.B., Ch.B. The Stark Scholarship in Clinical Medicine: Adam Cairns White. The McCosh Graduate's and Medical Bursaries: Harold Keith Corkill, M.B., Ch.B. The Beazley Prize in Anatomy and Surgery: Bruce Mackenzie Dick, M.B., Ch.B., and Thomas M. Walter Miller, M.B., Ch.B.—equal. The Mount Scholarship in the Practice of Physics: Carl Hercules Fouché, M.A., M.B., Ch.B. The Conan Doyle Prize: Carl Hercules Fouché, M.A., M.B., Ch.B. The Annandale Gold Medal in Clinical Surgery: Ian Gordon Cameron, M.B., Ch.B. The Buchanan Scholarship in Gynaecology: Bruce Mackenzie Dick, M.B., Ch.B. The James Scott Scholarship in Midwifery: Florence Lindsay Teller, M.B., Ch.B. The Scottish Association for Medical Education of Women Prize: Jessie Eccles, M.B., Ch.B. The Dorothy Gilliland Memorial Prize: Jean Margaret Thomson Connochie, M.B., Ch.B. The Wellcome Medals in the History of Medicine: Gold Medal, Thomas Ferguson, M.B., Ch.B.; Silver Medal, Frances Agnes Redhead. The Pattison Prize in Clinical Surgery: David Grievie. The Wightman Prize in Clinical Medicine: William Reginald Levie, M.B., Ch.B. The Cunningham Memorial Medal and Prize in Anatomy: Sidney Elizabeth Crookery, B.Sc. The Whiteside Bruce Bursary: George Brown.

UNIVERSITY OF LONDON.

The following candidates have been approved at the examinations indicated:

- M.D.—BRANCH I (Medicine): Dr. G. Chuvpcher, J. Fanning, W. H. Grace, P. W. Hamilton, D. Hunter, Kathleen McC. McKewen, A. G. Maitland-Jones, F. N. Moos, Jal P. Padshah, M. J. T. Wallis, F. E. S. Willis.
BRANCH II (Pathology): Charlotte I. Fox
BRANCH IV (Midwifery and Diseases of Women): G. F. Cooke, P. H. Mitchener, Lily D. Taylor, L. H. W. Williams.
BRANCH V (State Medicine): F. A. Knott, J. V. A. Simpson
BRANCH VI (Tropical Medicine): C. V. Boland, H. Hingston.
M.S.—BRANCH I (Surgery): J. G. Jones.

Chair of Pathology at Guy's Hospital.—Professor Adrian Stokes, D.S.O., O.B.E., M.D. (Dubl.), F.R.C.S.I., has been appointed to the Sir William Dunn Chair of Pathology tenable at Guy's Hospital Medical School. Professor Stokes served during the war in the R.A.M.C., and was for some time in charge of the pathological work in the 2nd Army in France. He was particularly concerned in the elucidation of the nature of the form of infective jaundice known as spirochaetosis ictero-haemorrhagica, a subject upon which he wrote in association with Dr. J. A. Ryle in this JOURNAL in 1916 (vol. ii, p. 413). Since 1919 he has been Professor of Bacteriology and Preventive Medicine in University of Dublin. Two years ago he worked with the Rockefeller Commission on Yellow Fever in Nigeria.

Histology.—The title of Reader in Histology has been conferred on Dr. C. D. Da Fano, M.D., L.D., Lecturer in Histology at King's College, and the title of Reader in Morbid Histology on Dr. G. W. de P. Nicholson, M.D., M.A., Lecturer in Morbid Histology at Guy's Hospital Medical School.

Out of the Thomas Smythe Hughes Medical Research Fund grants have been made for 1922-23 as follows: To Miss C. L. Houlton, M.D., B.S., of the London School of Medicine for Women, £100 for an investigation of vaginal secretions, with a view to the discovery of some prophylactic method for the prevention of puerperal infection. To Mr. V. R. Khanolkar, M.B., B.S., B.Sc., of University College Hospital Medical School, £25 for an investigation of the presence of non-specific antibodies against proteins, with a view to further insight into the nature of non-specific immunity.

Committee of Medical Members.—The Committee of the Medical Members of the Senate have elected Mr. Raymond Johnson, O.B.E., B.S., F.R.C.S., to be their chairman for 1922-23, in succession to Mr. H. J. Waring, M.S., F.R.C.S., who has been elected Vice-Chancellor.

UNIVERSITY OF MANCHESTER.

The following appointments have been made: Lecturer in Practical Surgery, Mr. Charles Roberts, M.B., B.S. (London); Clinical Lecturer in Mental Diseases, Mr. J. A. C. Roy, M.B., Ch.B., F.R.C.S. (Manchester).

The Platt Physiological Scholarship has been awarded to Mr. Harry Zwarenstein.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

At a meeting of the College held on July 24th the following successful candidates, having passed the requisite examinations, were admitted Fellows:

- J. Allison, J. A. Berry, G. S. Davidson, D. G. DuJ., W. F. T. Haultain, W. O. Lodge, J. Macarthur, J. M. Macpherson, V. Mahadevan, H. I. Marriner, J. B. Morrison, F. F. Petersen, Margaret S. Purce, W. Waddell, W. O. Walker, C. H. Wan, M. White, R. H. Williams.

Dr. J. Rao, L.M. and S.Univ. Calcutta, having passed the requisite examination, was admitted L.R.C.S.Ed.

CONJOINT BOARD IN SCOTLAND.

Final Examination.

The following candidates, having passed the Final Examination, were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:

- W. H. Lloyd-Worsley, Chong Tak Nam, A. K. Tateson, A. C. A. Fernando, M. G. L. Lucas, J. M. Somasundaram, W. A. B. Clark, M. Macleod, M. Widdin, C. W. de Villiers-Brichard, Agnes T. Martin, W. A. McE., Stewart, H. F. Appleyard, W. Gray, W. D. Oswald, I. B. Cummings, and H. G. F. Cubitt.

CONJOINT BOARD IN IRELAND.

At the Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons the following candidates have been successful:

FINAL PROFESSIONAL EXAMINATION.—M. P. Moran, E. M. Dodd, Henrietta C. Ball, J. P. O'Connell, F. E. Preston, W. E. Rutledge, W. Sherowitz, R. T. Taylor, The O'Rourke, J. S. Matthews, Maggie M. Nelson, Gladys C. M. Marshall, J. J. A. Loftus, D. S. Magner, J. T. Barrett, M. Levy, V. E. Lee, P. J. Greene, J. A. Flynn, P. Fleming, S. S. Brass, H. T. Beggs, Mary P. J. Conolly.

D.P.H. OXON., PART I: Correction.

Mr. Clement Duncombe calls attention to the misspelling of his name in the pass list published under the heading "University of Oxford" in the JOURNAL of July 15th (p. 111). It should be as now printed.

Obituary.

SIR EDWARD MALINS, M.D., M.Sc., F.R.C.P. (Lond.),

Consulting Obstetric Physician, Birmingham General Hospital; Emeritus Professor of Midwifery, University of Birmingham.

With regret we record the death in Birmingham on July 23rd of Sir Edward Malins, after a long illness. He was the youngest son of Dr. Samuel Malins, one of the founders of the Liverpool School of Medicine, and came of a family long associated with the city of Birmingham. He was born in Liverpool in December, 1841; he received his early education at King Edward's School, Birmingham, whence he went to Edinburgh University, where he took the degrees of M.B., C.M. in 1866, and that of M.D. in 1869. He became a Fellow of the Royal College of Physicians of London in 1902, and received the degree of M.Sc. from the University of Birmingham in 1901.

In 1872 he settled in Birmingham, and in 1877 was appointed obstetric physician to the General Hospital, a post which he held until 1903, when he was elected consulting physician. Throughout his life he took an active interest in the Birmingham Medical School and in the establishment of the Birmingham University. When the old medical school of Queen's College was transferred to Mason College in 1894 he was appointed professor of obstetrics, and continued to hold the chair when the College was merged in the University. He was professor altogether for eighteen years. He retired in 1912, and shortly afterwards was made Emeritus Professor. For five years he was secretary of the University of Birmingham Graduates' Club and its president in 1886 and in 1913. He held many other appointments in and about the city; he was surgeon to the Birmingham and Midland Hospital for Women, consulting obstetric physician to the Hammerwick Cottage Hospital and the Corbett Hospital, Stourbridge. He also took an active part in local medical organizations and was president of the Midland Medical Society 1882-83, and president of the Birmingham Branch of the British Medical Association in 1901. He was president of the Section of Obstetrics and Gynaecology at the annual meeting of the British Medical Association at Birmingham in 1911. His energy and capacity carried his influence beyond the city; he was examiner in midwifery and gynaecology to the Conjoint Board and the Universities of Manchester and Bristol, and had been president of the Obstetric Society of London.

His activities, however, were not limited to his professional work, exacting though it was. In 1893 he was appointed a justice of the peace for the county of Warwick, and in 1896 first filled the like office in the city of Birmingham. He was also a Governor of King Edward's School, and numbered among his past appointments: Chairman, Wm. Dudley Trust; Bailiff, Lench's Trust, 1908; Sands Cox Trustee since 1906; and for many years Vice-President of the Birmingham Conservative Association.

ARCHIBALD CAMPBELL MUNRO, M.B., D.Sc., M.R.C.P. (Edin.),
Medical Officer to the County of Renfrew.

EVERYONE connected with public health in Scotland will learn with sorrow that Dr. Campbell Munro has passed away. He was among the most prominent of the group of men who, under the newly passed Local Government Act of 1889, set to work to revolutionize the sanitation of rural Scotland. His own area was the non-burghal part of the thickly populated county of Renfrew. In those days it was necessary for the new medical officers not merely to justify their own unwelcome official birth, and educate their masters in the administration of existing laws, but to press also for extended powers, and at the same time to block legislative proposals

ostensibly progressive, but in effect retrograde. In all such efforts the Renfrowshire medical officer bore a splendid part. The outcome of the crusade was embodied in the Local Government Amendment Act of 1894, commonly called the Parish Councils Act, and the Magna Charta of Public Health in Scotland, the Act of 1897. As a preliminary to that great achievement it had been found necessary to block a burgh police bill which contained as much public health reform as would have satisfied the towns for a long time, and would have deprived a complete health measure for the whole community of the stimulus of burgh support. Dr. Munro was no less effectual in helping to hinder the one measure than in advancing the others, and in the end the public health part of the burgh police bill was unwillingly dropped by the Government, who found that the block would not be removed on any lower terms. It was stimulating and exciting work to those engaged in it.

Within his own area Dr. Campbell Munro made a marvellous change in respect of the elementary necessities—water supply, drainage, scavenging, house sanitation, and isolation hospitals—whilst in later years he followed this up in planting and fostering the newer developments of public health. No detail was so insignificant as to escape his personal attention: his energy was unbounded, and his monument to-day is to be found in the health of the county as he left it on his retirement some three years ago. Much of his work was done under the serious handicap of poor health, but physical weakness never evidenced itself in duty neglected or incompletely performed. He was a good pedestrian and a keen cyclist, so that much of his travelling was done independently of railway or motor conveyance. He was a clear and convincing speaker, and a very effective witness before a law court or a parliamentary committee.

When he retired he went to live in Edinburgh, of whose University he had been an honours graduate in 1874. Up to the end he continued to take a keen interest in the welfare of the Scottish Society of Medical Officers of Health, whose president he had been, and he was a valued member of the Scottish Midwives Board. He was a past president of the Glasgow and West of Scotland Branch of the British Medical Association and of the Sanitary Association of Scotland. The deepest sympathy of those who know him goes out to his wife and family in their irreparable loss. One of his sons—his own namesake—is in the Indian Medical Service.

DR. JOSEPH WILLIAM GAINER of Thrapston, who died recently, was born at Stonehouse, Gloucestershire, in 1858. He received his medical education at Edinburgh University, where he graduated M.B., C.M. in 1886 and M.D. in 1906. He began practice at Thrapston in 1888. He was medical officer and public vaccinator for the A district and workhouse of the Thrapston Union, certifying factory surgeon and honorary surgeon to the St. John Ambulance Association. Dr. Gainer took great interest in singing and was the first president of the local glee society. He suffered from a severe illness in 1919, which weakened his constitution and caused him to relinquish some of his professional work to his son Dr. Eric Gainer. In 1919 he was appointed a county magistrate and frequently sat on the Thrapston Bench. He was a member of the Northamptonshire Division of the British Medical Association and was held in high esteem by his private patients and by those whom he attended in his public capacities. He is survived by two sons and two daughters.

A MEDICAL centenarian, Dr. CHARLES HENRY BROOKING, died at Paignton on July 16th. He was born on April 3rd, 1822, and received his medical education at Guy's Hospital. He took the diplomas of M.R.C.S. and L.S.A. in 1843, and graduated M.D. St. Andrews in 1856. He formerly practised at Brixham, and is one of the last of the Volunteers of 1852; he commanded the Artillery Volunteers at Brixham in 1859. On the occasion of his attaining his hundredth year the Council of the Royal College of Surgeons of England sent congratulations to Dr. Brooking.

In the death of Dr. JAMES EDWARDS the north of Liverpool has lost one of its leading medical practitioners. He had been in indifferent health for some time past, so that his decease was not unexpected. Dr. Edwards was the fourth son of Principal Lewis Edwards, of Bala College, a minister of eminence in the Methodist Church. He studied at St. Bartholomew's Hospital, and became M.R.C.S. in 1879, after-

wards taking the Edinburgh L.R.C.P. and L.M. in 1881. He settled down in the north of Liverpool shortly after qualification, and through his assiduity and urbanity soon acquired a lucrative practice. He was a staunch advocate of temperance, and took a great interest in medical missionary work in connexion with the Welsh Calvinistic Methodist Church. He leaves a widow and a family of three sons and two daughters. One of the sons, Dr. Ivor Charles Edwards, has been in practice with his father since 1912.

DR. JACQUES BERTILLON, who had been statistician to the City of Paris for thirty years, died on July 4th in his 71st year. He was the son of Louis Bertillon, statistician, and the brother of Alphonse, esteemed the founder of anthropometry who died a few years ago. In the course of his statistical work Jacques Bertillon became impressed by the steady decline of the birth rate in France, and in 1896 established a society to stimulate interest in the subject. In 1918 he founded a bi-weekly journal, *La femme et l'enfant*. During the war he sought to impress on the French Government the importance of collecting and studying the statistics of diseases among the forces in the field, and was appointed director of the medico-chirurgical statistics of the French army.

THE well-known radiologist Dr. KEATING HART, who died in Paris last January, has been created posthumously a Knight of the Legion of Honour.

The Services.

PENSIONS CLAIMS.

WE are requested by the Ministry of Pensions to state the disabled officers, nurses and men, and the widows and dependants of those deceased, who desire to appeal to the Pensions Appeal Tribunal against the rejection of claims to pension, must do so on the prescribed form, within a year after the date of the notification by the Ministry of the rejection of the claim, or before August 19th, 1922, whichever is the later. Any new claim to pension in respect of disablement under any Warrant, Order in Council, or Order administered by the Minister of Pensions, must be made within seven years after the claimant was discharged, or before September 1st, 1922, whichever is the earlier.

HONORARY SURGEONS TO THE KING.

The following officers are appointed Honorary Surgeons to the King: Major-General B. H. Deane, C.I.E., I.M.S., vice Major-General the Hon. W. H. B. Robinson, C.B., I.M.S., deceased; Colonel H. A. Smith, C.I.E., vice Colonel J. Garvie, I.M.S., retired.

DEATHS IN THE SERVICES.

Captain Sadaana, Bashiam Venngopal, Indian Medical Service died at Poona on May 13th, aged 34. He was educated at Madras University and Guy's Hospital, and took the M.R.C.S. and L.R.C.P. London in 1914. He entered the I.M.S. as Lieutenant on August 1st, 1914, and was promoted to captain on March 30th, 1915. He served on the North-West Frontier of India in operations against the Mahand Waziris in May 1917, and against the Warri tribe in March-April, 1918.

Medical News.

A MEETING of the Dental Board of the United Kingdom was held on July 14th, with the Right Hon. F. Dyke Acland in the chair. It was announced that Mr. James H. Stirling had been nominated by the Lord Lieutenant of Ireland as a member of the Board in the place of the late Mr. John Sinclair. The Board passed a resolution informing the Minister of Health that in its view any hospital approved by one of the licensing bodies in the United Kingdom for the instruction of medical students, and the dental departments of any university of the United Kingdom, together with a list of schools of dentistry which were enumerated, should be approved under Section 5 (5) of the Dentists Act, 1921. It was resolved also that information should be obtained from the deans of dental schools regarding any students who have been unable to obtain a qualification in consequence of the expiry of Government grants prior to passing their final examinations, with a view to giving financial assistance in deserving cases. The Board also resolved that in the case of applicants for registration who were unable to comply with the requirements of the Act in consequence of service in His Majesty's Forces, it would be willing that July 28th, 1922, should be substituted for July 28th, 1921, where mentioned in the Dentists Act, 1921, in connexion with such applications.

At the present time the Royal College of Veterinary Surgeons has the sole right to hold examinations for admission to membership of the College. The Universities of London and Liverpool have sought the right to amend their charters so as to conduct corresponding examinations. The matter was argued before the Committee of the Privy Council on Wednesday, July 19th, Lord Dunedin, Lord Trevethin, and Sir Arthur Boscawen acting as the tribunal. Mr. J. D. Talbot, K.C., and Mr. Colam, K.C., were leading counsel for the College, and Mr. Tomlin, K.C., was for the University. The Committee came to the conclusion that the modification proposed by the Universities was *ultra vires*, and that the object sought could only be effected by legislation.

THE International Labour Conference (League of Nations) in a convention of last year laid down that after November, 1927, with certain exceptions as to railway stations and industrial buildings, white lead shall not be used in the internal painting of buildings. The Government of Tunis, unwilling to wait so long a period, have decided that within a year from now the use of white lead shall be prohibited in that country: in external as well as internal painting, and that white lead shall not be used in other operations except in the form of a paste. Further, that dry scraping and dry rubbing down, which is believed to be responsible for much of the lead poisoning occurring among coach painters, shall not be allowed.

THE first prescribed examination under the Dentists Act, 1921, was held at Manchester on July 11th and 12th, when 65 candidates presented themselves and 45 passed. Of the 15 war service candidates 4 satisfied the examiners in Part (1) only, and one in Part (2) of the examination.

THE tenth Italian Congress of Paediatrics will be held at Milan from October 1st to October 4th, when the following subjects will be discussed: Active and passive immunization against diphtheria, introduced by Dr. Pincherle of Bologna and Dr. Frontali of Florence; prophylaxis of tuberculosis in childhood, introduced by Professor Cannata of Messina. Further information can be obtained from Dr. Grassi, 9, Via Commenda, Milan.

PROFESSOR W. DUNBAR, a well-known authority on hygiene, has recently died at Hamburg.

THE house and library of the Royal Society of Medicine will be closed during August.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London; (telephone, ...)

Medisecra, Westrand, London; tele-
phone of the Irish Office of the British
Frederick Street, Dublin (telegrams:
7, Dublin), and of the Scottish Office,
(telegrams: Associate, Edinburgh);

QUERIES AND ANSWERS.

INCOME TAX.

"W. G." purchased a 29.5 Hudson car in 1920 for £995. He has just bought a new F.I.A.T. for £550, the agents allowing £330 for the Hudson.

"The amount allowable does not exceed the out-of-pocket cost of replacement, and consequently "W. G." cannot claim more than £550-£330=£220. That sum is a professional expense of the year in which the transaction took place, and presumably will not affect his average income tax liability for the present financial year.

"W. H. L." has purchased a partnership, and is told that he must pay his share of income tax on the debts collected and handed over to his predecessor. He asks whether this is correct.

"Yes. The practice is evidently assessed to income tax on the usual basis of cash receipts—that is, the earnings of any particular year are measured by the cash received in that year instead of by the value of the fees booked. Although the tax to be paid by "W. H. L." is measured by the receipts from his predecessor's work, the "income" that is being assessed is the result of his own work in the year for which the assessment is made.

AN OLD WIFE'S FABLE.

DR. DAN McKENZIE (London) writes: In reply to Dr. J. B. Hellier's question regarding the advice given to a newly confined woman "to go upstairs before going down," permit me to say that this is a very general superstitious practice, dependent upon sympathetic magic. If the mother or the baby or the invalid goes up, his or her health will also go up, and vice versa. There is of course no rational basis for these quaint ideas, but we are all subject more or less to their influence and must constantly be on the watch to avoid their power, for they spring from the same weedy corner of the human mind as what we know so well in scientific matters as "the personal element." If Dr. Hellier would like further information on this subject he will find enough in Sir James Frazer's *Golden Bough* to keep him busy for many weeks.

LETTERS, NOTES, ETC.

PSYCHO-ANALYSIS IN EPILEPSY.

DR. S. F. McDONALD, M.R.C.P. (Brisbane), writes: A very great number of statements are being made at present praising the value of psycho-analysis in many forms of nervous disease. Having had a little experience of the extreme value of such treatment I am the more anxious that it shall not be allowed to gain disrepute by wild statements such as that at present being made about epilepsy. Those of us who have the misfortune to deal with epilepsy are only too anxious for any help at all in the matter—but we want solid facts. To say that an epileptic fit is a withdrawal from reality and a means of escape sounds splendid, but does it help us in treatment? We are told that this has been demonstrated by analysis: has it been demonstrated in the case of children?—for example, in a child of 5 with alternating attacks of grand and petit mal, which are only restrained by luminal. Again, in congenital syphilis one sees epileptiform attacks, indistinguishable from true epilepsy, which disappear with anti-syphilitic treatment. Can I extract from any of those now practising psycho-analysis even a few figures showing number of cases analysed, finding and results from analytic treatment? Every other method must submit to such a test: why not psycho-analysis?

RAT-BITE FEVER.

MR. V. N. MEHTA (Bombay Presidency, Viramgam) writes: I had recently a case of rat-bite fever, presenting all the typical symptoms after an incubation period of fifteen days—namely, swelling and inflammation at the bitten part, formation of vesicles, erythematous rash over the arm and abdomen, shooting pains in the joints, and a rise of temperature which continued for about a week, ranging from 104.5° to 100°. Throughout neo-salvarsan was to be injected, but owing to the high fever it was delayed till the apyrexial stage after a week, when 0.45 gram novarsenobillon was injected intravenously and the patient has since made very satisfactory progress. Our correspondent concludes by asking whether neo-salvarsan, in cases of rat-bite fever, can be injected during the pyrexial stage, and in that case up to what temperature it may be considered quite safe to inject?

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 32, 33, and 34 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 64.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive postal telegraphic letters addressed either in initials or numbers.

NINETIETH ANNUAL MEETING

OF THE

British Medical Association.

Held at Glasgow, July, 1922.

PROCEEDINGS OF SECTIONS:

SECTION OF MEDICAL SOCIOLOGY.

E. ROWLAND FOTHERGILL, M.B., B.S., President.

THE PRESIDENT, in opening the proceedings of the Section, said that some twelve years ago the British Medical Association decided that amongst the other Sections at the Annual Meeting it should include one—the Section of Medical Sociology—to which the laity might be invited to contribute to discussions. The question of alcohol had been chosen on the present occasion, but it was obviously a subject on which the limits of discussion must be strictly defined. The question was:

“To what extent, if any, can alcohol as a beverage be considered to have any influence on the human economy, mental disorders, industrial efficiency, and infant mortality?”

DISCUSSION ON

ALCOHOL AS A BEVERAGE AND ITS RELATION TO CERTAIN SOCIAL PROBLEMS.

THE ACTION OF ALCOHOL ON THE HUMAN ECONOMY.

BY

EDWARD MELLANBY, M.A., M.D. Cantab.,
Professor of Pharmacology, University of Sheffield.

THE advantages of alcohol as a beverage are so obvious to some and its disadvantages so thoroughly realized by others that, until recent years, scientific discussions of an impartial nature of problems centring round it were rare. It seemed to the average man to be a subject which required no special knowledge in order that he should either strongly favour it as a great blessing to mankind or denounce it as the greatest curse. Fortunately the point of view is gradually altering, and, while we realize that the problems presented by alcohol in its relation to human existence are of the most pressing importance, we also believe that a true judgement can only be arrived at by a careful consideration of the facts.

As a preliminary to the more interesting papers and contributions to the discussion of the social problems which we are to hear to-day, and as affording a foundation for such discussion, it is my duty to describe some of the fundamental facts as to the action of alcohol on the human economy and to supply a summary of the views generally held by those who have made a close study of the pharmacology and therapeutics of alcohol.

Alcohol may be considered from various aspects—for instance, as a beverage imbibed extensively by healthy people, or as a medicine taken in sickness. It must be admitted that, whatever the point of view, our knowledge of the subject is still meagre. We have some knowledge of its action in health, but we cannot be certain that the known facts are always sufficient to explain its action in disease. It is probable that many of the effects produced by alcohol in health and disease can be similarly explained, and that the basis of its action in both cases is generally the same, but this does not mean that it is always the same. Some such warning seems necessary at the beginning of this discussion, for there is still much difference of opinion among those well qualified to judge as to the action of alcohol in various diseases, and it is probable that these differences do not depend on prejudice but on our limited knowledge. This point will be referred to again after the action of alcohol on the nervous system has been discussed and when its therapeutic properties are being considered.

It will be well at the outset to distinguish carefully between two properties, of a diverse and apparently independent nature, possessed by alcohol, both of which will be encountered in any discussion on the subject, either from a medical or sociological point of view. In the first place, if a food be

defined as that which can supply useful energy to the body, then alcohol is a food. Secondly, in that alcohol has the property of modifying the function of living matter, it must be regarded as a drug. Alcohol is, in fact, to be classified as a food-drug. I shall consider these two properties of alcohol separately, taking the drug action first.

By far the most important action of alcohol as a drug depends upon its power to modify the functions of the nervous system. The special affinity of alcohol for this system is thought to be due to its high lipid content, thus allowing the easier access of alcohol into the nerve cells. The fact that in discussing the action of alcohol attention is usually fixed on its power to modify the functions of the nervous system is no doubt due to the ease with which such modification of function can be detected. The activities of other organs are also altered by alcohol, but such changes are usually more difficult to detect, and only appear to be of sufficient interest to merit attention in acute and when the structure of the organ.

Alcohol is a popular beverage because of its property of inducing changes in the nervous system which are the basis of the altered sensations and outlook sometimes described as euphoria. Many investigations and much discussion have centred round this action. The effects are apparently very contradictory; whereas drowsiness is often produced even by the smallest doses, at other times excitement is more evident, and even in the same person periods of drowsiness and excitement may alternate according as the environment changes. There is but little wonder that two schools of thought have arisen among those studying the problem, one regarding alcohol as primarily a stimulant to the nervous system, and the other, led by Schmiedeberg, as a depressant in action from the first. This discussion might have been interminable had it not been that in recent times our knowledge of the functions and mode of action of the nervous system has developed to an extent which allows us to get a better understanding of the symptoms produced by alcohol, and to place in alignment facts which formerly seemed so contradictory. We know now that the outstanding function of the cerebral cortex is to restrain and inhibit many of the activities of the lower and earlier developed parts of the nervous system. It allows us to judge and to discriminate, and, by directly influencing the thalamus, controls our emotions. It is the great brake, both as regards activities associated with conscious effort and in those more automatic. It exerts a constant influence on the paracerebellar nuclei, thereby antagonizing overaction of the cerebellum, and, by bringing to bear a steady effect on the spinal cord, it prevents spastic and inco-ordinate movement. Thus it is obvious that any narcotic whose primary action is to paralyse this part of the nervous system will produce just those symptoms which are seen in alcoholic intoxication. As the direct result of narcotizing the cells of the cerebral cortex we can easily understand the loss of judgement, memory, power of association, and the increased tendency to sleep. Similarly, the impairment by alcohol of delicate actions associated with concentration and mental effort—such, for instance, as setting up type and shooting at a target—can be explained along these lines. It is most noteworthy that the above-described effects of alcohol are produced by small doses, say 1 oz., when no one would suggest intoxication, or even suspect, from the general demeanour of the person tested, that alcohol had been drunk. In fact, in order to detect these changes produced by small quantities of alcohol, accurate scientific experiments must generally be made.

But in addition to these fairly self-evident facts we can now understand some of the nervous effects of alcohol on the emotional side, since we know from Head's work that the thalamus is particularly related to the emotions. Small quantities of alcohol by depressing the higher centres release the brake on the thalamus and so allow freer play to the emotions. Feelings of joy, misery, anger, and excitement are more easily called forth, and with cares and worries forgotten a feeling of light-heartedness usually develops. Self-consciousness and self-criticism are depressed by alcohol, and for this reason alcohol may make apparently ordinary people talk in a clever and interesting way and shy people bolder. All the latter results, which at one time were regarded as evidence of a stimulating action of alcohol, are now generally regarded as being the result of depression and partial paralysis of a normal-inhibitory mechanism.

It is interesting to note that, unlike morphine, which picks out and depresses primarily that part of the brain which appreciates sensation, alcohol does not seem to have any selective effect in acting on the cerebral cortex. Whereas a

man is cut off to a great extent from his environment by morphine, so that his thoughts are largely concerned with past experiences, alcohol in moderate quantities has no such effect on the sensorium, and under its influence a man's thoughts centre round and are easily affected by his immediate surroundings.

With larger doses of alcohol the action on the nervous system is more obviously depressant—greater inco-ordination of movement, more or less anaesthesia, depression of reflexes and of the respiratory and other centres all appearing and becoming more strongly developed.

It is clear that alcohol must be placed among the narcotic drugs so far as its action on the normal human organism is concerned. To class alcohol as a narcotic may seem to some people to put it out of court as a substance capable of usefulness either as a beverage or as a therapeutic agent. This seems to me to be a wrong view, for narcotics have their sphere of usefulness just as certainly as have stimulants. Modern conditions of life, with its competition, acquisitiveness, and restlessness, have many undesirable features which make existence almost intolerable to many people. Alcohol is taken as a beverage by the average man in order to escape, at least for a time, from the strain of existence. Small quantities of alcohol are capable of dispersing temporarily many of the worries and troubles of life, and so may play a part in restoring to better working order various functions of the body whose action is known to be depressed by anxiety. For instance, nothing is more certain than that worry has a depressing influence both on the secretion and movement of the stomach, and thereby may induce or exaggerate a dyspeptic condition. Some cases of dyspepsia of this type may be favourably influenced by dilute alcoholic beverages, which obliterate the worry and so remove the factor responsible for the reduced secretion of gastric juice and the sluggishness of movement of the stomach walls.

Dale has recently suggested that the narcotic action of alcohol on the nervous system probably accounts for the instances where it is regarded as having a beneficial effect in disease, and where such an influence cannot readily be explained along lines compatible with its recognized pharmacological action. He argues that in sick people the functions may be depressed not only by actual weakness but by inhibition due to reflex action or to influences from the higher centres. For instance, in syncope due to fright or pain the heart and vasomotor centre are undoubtedly subjected to severe central inhibition, and alcohol may have a beneficial effect in these conditions because it weakens and removes this inhibition by its narcotic action. From the point of view of experimental pharmacology it has been difficult to understand some of the actions of alcohol described by clinicians in heart failure associated with pneumonia, typhoid, and other diseases. On the one hand, evidence of a direct stimulant effect of alcohol on the heart is not satisfactory, while, on the other hand, the beneficial effect of alcohol in some cases of heart failure is too widely accepted to be passed over lightly. The suggestion that the beneficial effect in these cases may depend on the power of alcohol to depress excessive inhibitions is worthy of further consideration. Dale has also pointed out that if rapid, shallow breathing produces anaemia and the baneful effects as stated by Haldane, then alcohol, by slowing the respirations and making them deeper, may be beneficial in diseases where this type of breathing occurs.

To sum up, although alcohol can no longer be regarded as a stimulant except in so far as it irritates the nerve-endings of such organs as the mouth, oesophagus, and stomach, its effects, whether as a beverage or as a medicine, may be no less important, even though they are to be explained by its narcotic action on the central nervous system.

ALCOHOL AS A FOOD.

I shall now deal with alcohol as a substance capable of supplying useful energy to the body. It was shown by Atwater and Benedict, that nearly all alcohol, when drunk in moderate quantities, is completely oxidized in the body, and that only quantities of the order of 2 per cent. escape unchanged in the urine and expired air. Since the oxidation of 1 gram of alcohol gives rise to 7 calories of heat, as compared with 4.1 calories produced when either 1 gram of protein or 1 gram of carbohydrate is oxidized, it is evident that, if we can overcome the toxic effects of alcohol, the amount of energy it can supply to the body ought to be large. Alcohol has a further advantage in that it requires no digestion and is rapidly absorbed from the stomach and alimentary canal.

Two questions that require an answer are: (1) How much energy can alcohol supply to the body? (2) What is the best way to give alcohol in order to obtain the maximum amount of energy with the minimum of toxic action?

As regards the first question, some idea of the energy supplied by alcohol oxidation has been obtained by Voit and Dietrich, who showed that in resting dogs 42 per cent. of the total energy was supplied by alcohol in a ten hours' experiment, and 35 per cent. in a fifteen hours' experiment. In one of my own experiments a dog weighing 13.5 kg. was given 50 c.cm. of alcohol in a 20 per cent. solution. This was oxidized in twenty hours, as shown by the fact that after this time the blood was alcohol-free—that is to say, 2.5 c.cm. of alcohol were oxidized each hour, thus supplying to the dog 1.04 calories of heat per kilogram body-weight per hour. This represents about 40 per cent. of the total heat lost during the period. A similar experiment on a man may be described. He drank in half an hour whisky containing 171 c.cm. of absolute alcohol (he could have drunk this quantity easily in five minutes). His weight was 70 kg. The amount of alcohol in his blood was estimated at intervals, and from the curve obtained the rate of oxidation of alcohol in his body was calculated. It was found that he oxidized about 10 c.cm. of alcohol an hour, and was thus supplied with 54 calories an hour, or, roughly, at the rate of 1,300 calories per diem. This would represent about 40 per cent. of his total heat loss.

In the above-described experiments on the dog and man, although a surprisingly large amount of energy was supplied to the organism by alcoholic oxidation, from the point of view of medicine the results are of but little interest, for intoxication of a severe degree was produced in both cases. Later I shall describe how the toxic symptoms can be eliminated and yet the body be supplied with a large amount of energy from alcohol.

I have shown in a previous publication that the rate of oxidation of alcohol in the body is independent of the amount present in the blood over fairly wide limits. The rate of disappearance of alcohol from the blood is almost the same in dogs, whether a large dose sufficient to produce profound intoxication (say 50 c.cm. of alcohol) or a much smaller dose (say 20 c.cm.) is given. This fact had previously been demonstrated by Higgins, using another method, for he found the respiratory quotient of man to be depressed to the same degree by 30 c.cm. and by 45 c.cm. of alcohol. Carbohydrates and fats do not act as foodstuffs in this way, for their influence on the respiratory quotient varies with the amount eaten. This difference between alcohol and other foodstuffs is important both from a scientific and a practical point of view.

As mentioned above, the man of 70 kg. weight when at rest oxidized 10 c.cm. of alcohol an hour, so that if the constant rate of oxidation holds also for very low concentrations, it would only be necessary to give doses of about 10 c.cm. an hour in order that the maximum amount of energy in unit time be obtained from the oxidation of this substance. The smaller the dose the less toxic the action, so it may be possible to get out of alcohol the maximum amount of energy in unit time and escape the effects due to its drug action. Experiments have proved this to be the case.

It is now well recognized that the food properties of alcohol can be made use of to the best purpose in diabetes mellitus. In the modern treatment of this disease the diet is so arranged that the urine is kept sugar-free, but in severe cases this generally means that the diet is extraordinarily small from the point of view of energy. When any attempt is made in such cases to increase the amount of food, sugar excretion usually commences. Alcohol can be oxidized by these diabetics without causing the production of sugar, and so is a useful adjunct to the dietary for supplying energy.

Sontag and I have recently investigated the best way to supply alcohol to diabetics of this type, and have found the amount of energy that can be provided without production of toxic action. The details of this work will be published elsewhere. We corroborated and made use of the fact discussed above and suggested by the animal experiments, that, even when small quantities of alcohol are drunk, the rate of oxidation is not greatly reduced. We found the amount of alcohol the diabetic patient could oxidize each hour, and then gave this quantity hourly throughout the day. The amount varies with the weight of the patient, and whether he be confined to bed or living an active life. The alcohol burnt up by the average diabetic is of the order of 7 to 10 c.cm. an hour. By this method of administration no symptoms of alcoholism are produced, for the alcohol in the blood and

nervous system is never more than a trace at any time of the day. If the amount is increased beyond that oxidized there will be a slight accumulation of alcohol in the body and the patient may become drowsy and sometimes flushed late in the day, but this can be avoided by reducing the amount. Thus, allowing the patient eight hours' sleep, a small dose of 7 c.cm. of alcohol or thereabouts can be given each hour for sixteen hours; in which case 112 c.cm. of alcohol are oxidized, supplying 630 calories of heat. This is a minimum, and in practice larger quantities of energy can be obtained from alcohol in specific cases. The energy supplied in this way without producing toxic symptoms or increasing the sugar in the blood makes all the difference to the treatment of severe cases of diabetes, and allows the patients to live a more active life and at the same time retain their weight.

It is most important in giving alcohol for therapeutic purposes, especially if drunk repeatedly and over any length of time, to dilute it well. In some cases, no doubt, the therapeutic effect most desired in prescribing alcohol is its irritant action on the mucous membrane of the mouth, oesophagus, and stomach. But it is usually necessary to eliminate this irritant effect, and in this connexion it may be stated that alcohol in concentration of 10 per cent. or over will produce gastritis if taken repeatedly, especially on an empty stomach. In diabetes, for instance, it ought to be diluted to 5 or 6 per cent. strength. Even where the drug action of alcohol is required for therapeutic purposes, except when it is specifically given as an irritant, it is best given in a dilute form; dilution of quantities up to 30 c.cm. makes but little difference to the intensity of its action. Vernon tested the relative effects of drinking 30 c.cm. of alcohol in 40, 20, and 5 per cent. solutions on the efficiency of typing memorized passages, and found that the 5 per cent. solution resulted in three-quarters of the increase in errors produced by the 20 and 40 per cent. solutions. Therapeutic doses of alcohol, its effect as of the stomach is lost, but its action is greatly affected. It will be seen later that dilution becomes of still greater importance when larger quantities of alcohol are imbibed.

The foregoing facts as to the food value of alcohol throw some light on the condition of corpulency so commonly found among chronic alcoholics. While there is no evidence that alcohol itself is converted into fat, we have seen that it replaces and conserves fat already present in the body. In the case of malt beverages the constituents other than alcohol are an additional source of energy and their carbohydrate quota is readily converted into fat. Another factor of importance in this connexion is that alcohol diminishes activity by its narcotic action on the nervous system, and for this reason also encourages the accumulation of fat.

To sum up, alcohol can supply a large amount of energy to the body both in health and disease. This can be made use of especially in diabetes mellitus. In giving alcohol as a food in disease it is important to reduce to a minimum its drug action. This can best be done by (1) giving small doses frequently—for instance, hourly doses of 7 to 10 c.cm. that can be oxidized in this time, and (2) by diluting it down to about 5 per cent. strength.

ALCOHOL IN STARVATION AND EXPOSURE.

Considering the amount of energy that can be supplied to the body by alcohol, it might be thought that in the treatment of starvation and exposure this substance would have great merits. This idea is increased by the knowledge that alcohol in these conditions brings a sense of comfort such as no other drug can bring. The skin vessels are dilated by the alcohol, a sense of warmth pervades the body, and, in addition, anxiety and worry are forgotten. There is but little wonder that in these conditions alcohol is often regarded as a panacea. In some cases this is true, but in others the giving of alcohol is bad practice. We must see what the closer study of alcohol teaches in this matter.

While it is true that alcohol can supply a large proportion of energy to the body, it is different from other foodstuffs in that it has no stimulating effect on the metabolism. In other words, alcohol has no specific dynamic action, while, according to Rubner, the specific dynamic action of meat protein is 44, of fat 16, and of carbohydrate 10. Suppose, for instance, a man is starving and alcohol alone be given him, his production of heat will not increase. If he is given carbohydrates his production of heat will increase slightly. If given protein, the metabolism will be greatly stimulated. Although alcohol supplies heat as the result of its combustion, it does not make

any more energy immediately available for the body; while protein, which gives less heat on combustion, stimulates the metabolism and affords an immediate increase in available energy. Alcohol conserves the stores of protein, fat, and carbohydrate. In the case of the starving man to whom alcohol is administered its first effect is to dilate the cutaneous blood vessels, thereby allowing a rush of blood through the skin. This affords a feeling of warmth and well-being but, by increasing the temperature of the skin, increases the heat loss. Since alcohol does not increase the metabolism, if no other food be available it is clear that the temperature of the body must fall, for the increased heat loss is not counterbalanced by increased heat production. If the alcohol also induces drowsiness and exerts its narcotic action on the neuro-muscular mechanism, the heat production may be still further reduced, with a corresponding increase in fall of temperature, and death may ensue. We see, therefore, that in cases of hardship and exposure, alcohol ought never to be given or taken unless there is an immediate possibility of obtaining more food and shelter. Where additional food and warmth are attainable, alcohol as a means of producing an immediate sense of comfort may be justifiable since the above reasons against its administration are no longer present.

ALCOHOL AND HEREDITY.

I wish now to refer briefly to the work of Stockard, whereby facts of apparently fundamental importance as regards the relation of alcohol to certain problems of heredity have been brought to light. There has long been in the minds of people the idea that toxic substances such as alcohol and the virus of syphilis may injure germ cells in such a way that the progeny, not only of the exposed parents but also of the unexposed succeeding generations, are abnormal. Stockard's investigations appear to lend strong support to these views and to supply a means for working out the subject by a scientific method. By placing male guinea-pigs in air containing alcohol vapour for periods of one hour each day—that is to say, until they are completely intoxicated—for six days in the week, and then crossing them with untreated normal females, Stockard was able to show that the progeny are often aborted, and that of those surviving there is a high percentage of abnormalities, including (1) absence of eyes, (2) defect and sometimes absence of brains, (3) nervous symptoms of the nature of paralysis agitans. These abnormalities, which must be the result of damage to the male germ cell, may be transmitted through several generations, although none of the succeeding parents are again exposed to the alcohol vapour. The damage to the germ cell is, in fact, transmitted to the offspring, and only slowly returns to the normal through succeeding generations.

The treatment of the male guinea-pigs was very severe, and an analogous state could only be found in human beings in very exceptional cases. Before these results are accepted as being directly applicable to man further careful inquiry and investigation must be made. But to have put a problem of this type on to an experimental basis seems to me to be an achievement of great value.

ALCOHOL AND DRUNKENNESS.

So far I have dealt with the effects produced by amounts of alcohol that could reasonably be given for therapeutic purposes, and I shall now deal with drunkenness, and briefly discuss some of the conditions which influence the development of this condition. Undoubtedly the same factors also influence the slighter effects of alcohol, but they become more prominent, and are more easily studied, in connexion with pronounced degrees of intoxication.

1. Size.

It takes more than the proportionate amount of alcohol to raise the alcohol concentration in the blood to a definite point in the case of a large animal, and especially a large fat animal, as compared with a small animal. If this result applies to man, as it probably does, then supposing there were two men, A and B, of weight 7 st. and 15 st. respectively, all other conditions being equal, it would be necessary to give B more than twice the amount of alcohol drunk by A to make them equally drunk. The corpulency and size of the chronic alcoholic is undoubtedly largely responsible for his apparent tolerance.

2. Dilution of Alcohol.

Whereas with small quantities of alcohol the rate of absorption into the blood stream and therefore the symptoms

of intoxication do not greatly differ whether it is drunk as a 5 per cent. or a 20 per cent. solution, with larger quantities such as will produce drunkenness the concentrated solution is absorbed more rapidly and reaches a higher maximum in the blood. Corresponding to this, the degree of intoxication produced by the strong solution is more intense. These differences in intoxication dependent upon concentration hold even when all the alcohol in each case is imbibed in the same time. In practice, however, another factor is introduced with dilution which is of greater importance in comparing the intoxication symptoms produced by weak and strong alcoholic solutions—namely, time of drinking. The volume of a concentrated alcoholic solution, such as whisky containing 20 per cent. alcohol, necessary to produce the most profound degree of intoxication can be drunk in a few moments, whereas to imbibe the same amount of alcohol in a dilute form such as beer may take hours of steady drinking. During these hours alcohol already absorbed is being oxidized, thereby preventing the alcohol concentration in the blood ever attaining the high maximum which is found in the case of the concentrated solution. The relative intoxicating power of concentrated and dilute alcoholic beverages—for example, whisky and beer—is very different when their action on man is compared, but the problem is not a simple one, and limitation of space prevents further discussion here. Diluting an alcoholic beverage already dilute—for instance, converting a 5 per cent. into a 3 per cent. beer—makes a very great difference in the intoxicating power for the same reasons. I have seen no evidence that there is any truth in the popular belief that mixed drinks have special intoxicating properties except in so far as more of each beverage may be drunk or the average concentration of alcohol increased.

3. The Influence of Food.

Food in the stomach and alimentary canal has a great influence on the absorption of alcohol into the blood stream, and therefore on the symptoms of alcoholic intoxication. Practically all foods have some effect in inhibiting the absorption, but milk stands in a pre-eminent position. Nor is it necessary that the milk be drunk with or immediately before the alcohol. Some inhibiting influence is seen even if taken as long as four hours beforehand. Experiments demonstrate that the most important inhibitory factor in milk is the fat. These results have been extended to and confirmed in man. The extent to which milk can modify or eliminate the worst symptoms of alcoholic intoxication is most striking. The popularity of a combination of rum and milk among north-country men is a clear indication that the empiricist has arrived at this fact before the scientist.

4. Intervals between Drinks.

If it is desired to reduce the symptoms of intoxication by introducing an interval between drinking periods instead of by diminishing the amount of alcohol drunk, then this interval ought to be long. The fact that the interval must be long depends on the slow rate of alcohol oxidation in the body as compared with the size of the intoxicating dose. After a good carouse it will take ten to eighteen hours for the alcohol to be cleared out of the circulation of a man. Its presence in the blood indicates the reason for the lack of appetite at breakfast on these occasions.

5. Effect of Exercise.

Muscular exertion increases the rate of oxidation of alcohol in the body and hastens its departure from the blood. With small quantities of alcohol in the body exercise increases its combustion at the same rate as that of carbohydrates and fats (Atwater and Benedict). With larger quantities, when its toxic action is greater, exercise does not bring about the same increase in rate of oxidation. A person taking exercise can drink larger quantities of alcohol than one leading a sedentary life because the rate of combustion is increased by the exercise. In conditions of inebriation walking "works off" the effects more rapidly. Probably a part of this action is due to the better opportunity of the central nervous system to restore a perfect co-ordinating mechanism as the result of practice, and partly to the increased rate of combustion of alcohol in the body due to exercise.

6. Tolerance.

So far as my experience goes, tolerance as regards alcohol is insignificant as compared with that which develops in the use of morphine. I have seen no evidence that the rate of oxidation is increased in those continually drinking alcohol,

nor, if it is taken under constant conditions, have I seen evidence of the development of great tolerance. It remains true, of course, that many factors influence drunkenness—such as the rate of drinking, dilution, size and fatness of the individual, and the amount of exercise being taken. Even the novice can take large quantities of alcohol in the course of a day without being at all intoxicated if he takes it in the right way. If all the circumstances under which the habitué drinks be investigated, and the various influences described above be allowed for, it will be seen that alcohol tolerance is less than is usually thought.

GENERAL DISCUSSION.

PROFESSOR A. R. CUSHNY (Edinburgh) said that the discussion on this subject was to have been opened by the late Dr. Rivers, of Cambridge, whose untimely death they all deplored. Rivers had done some admirable work on the alcohol problem; he was the first to show that in examining the action of alcohol it was necessary to use controls. The discussion would be the poorer for his absence. He himself agreed almost completely with Professor Mellaub's argument. In connexion with the long-disputed question of the food value of alcohol, he recalled the storm which arose when Atwater and Benedict propounded their results. He thought that everyone now recognized that alcohol had some food value—that is to say, it really could yield energy. The body was able to use alcohol as a source of energy just as an engine used coal. This, however, did not mean that alcohol was a desirable food or one to be recommended. Professor Mellaub had given an extreme case in which the value of alcohol had been demonstrated, but that was a medical case, and did not refer to a normal condition at all. Many things could be used to give energy to the body, but regard must be paid to their effect upon the body in other ways as well, for some of them had a poisoning action. Green apples undoubtedly gave energy to the body, but it was a question whether they were good food. Although alcohol conferred energy, it weakened the brain. It was a food, but it was also a poison or a drug. He thought also that the value of alcohol as a food had been greatly exaggerated of recent years. The amount of food to be obtained in alcohol was surprisingly small. A good ordinary pre-war beer, which might be taken as a type, was about equivalent, pint for pint, in food value to a good sweetened cup of coffee containing milk. No one imagined that when he partook of his breakfast cup of tea or coffee he was absorbing a food of any particular value, and the value of beer was no greater. Nevertheless, in certain conditions, notably diabetes, alcohol might be very useful for its food value in a specific case.

The Rev. C. C. WEEKS, M.R.C.S. (Beckenham), said that human economy might be defined, generally, as relating to the science and art of managing the concerns and resources of society and its constituent units, so as to secure the highest degree of efficiency and well-being, and particularly to the operations of nature in the generation, nutrition, and preservation of life or the system under which the functions in health and disease were performed. The present rate of alcoholic indulgence was undoubtedly a powerful coefficient of disease and inefficiency, and when opportunities for drinking were restricted there was a marked diminution of all the conditions thought to be associated with alcoholic indulgence. It had to be remembered, also, that during the last hundred years a great body of experience had arisen as to the value of total abstinence. Professor Cushny's statement that although alcohol had some energy value it was not a recommendable article of food was well borne out by a reference to modern textbooks of physiology, where it was quite well recognized and agreed that alcohol did not repair, build up, or renew the tissues, did not increase the rate of absorption of food, did not promote body temperature, tended to upset the water balance of the cells, had no specific dynamic action, could not be stored in the body for future use, and failed to co-operate with other foodstuffs in stimulating the metabolic processes. On the other hand, alcohol was costly to produce and to purchase, and costly in its effects upon the human organism.

Dr. CHARLES F. HARFORD referred to a paper he had contributed to the Society for the Study of Inebriety on racial psychology in its relation to alcoholism, in which he had put forward a theory of drug dissociation, to which he desired to return. The term "dissociation" was a fundamental one in

psychopathology, but it was not always used in the same way by different teachers, and he himself would give it a wider meaning than many. Cases which had been recorded under the heading of multiple personality were among the most conspicuous instances of this state, but a similar condition was produced by hypnotism, and in a sense there was a definite dissociation taking place in natural sleep. Obviously the condition was not always a morbid one, though in extreme forms it was one of the most striking signs of insanity. After relating particulars of a recent case in which a man convicted of fraud had put forward the defence that he was influenced by alcohol in such a way that it amounted to a case of dual personality, so that he was irresponsible for his actions—a plea the magistrates did not accept—the speaker went on to show that this process of dissociation was common to each stage of the alcohol habit. Three stages were described in the manual published by the Liquor Control Board, *Alcohol, Its Action on the Human Organism*. The first was a feeling of well-being, with a blunting of self-criticism, instanced by a public man, burdened with many cares, who delivered himself of a vivacious and rather irresponsible after-dinner speech, in which he seemed at peace with the world and oblivious to common cares. Dissociation was met with here at an early stage, but it was an important step in a habit which might assume a very different complexion. The power of concentration on one thing, and exclusion of others, was of the essence of self-control, but an artificial dissociation produced by alcohol and kindred drugs tended to weaken the control which was one of the primary factors in sanity and health. To adopt the phraseology of Freud, the “pleasure principle” under the influence of alcohol was in the ascendant, while the “reality principle,” which should have served as a drag upon the wheels, was failing to fulfil its purpose. The second stage might be described as that of neutral self-satisfaction, disregard of conditions normally evoking caution, trespass of conventions previously respected, impaired appreciation of the passage of time, loquacity, and mind. This stage was definitely pathological.

Every one of its distinguishing marks characterized also the cases in mental hospitals. These people were insane, but owing to the fact that the cause of the condition was known to be the taking of alcohol, and the symptoms were temporary, they were spoken of as intoxicated. This was a stage in which dissociation was most clearly marked; the “pleasure principle” had asserted itself, while the “reality principle” had become thoroughly ineffective. The third stage was an accentuation of all these symptoms, leading to somnolence and insensibility, or even to delirium. This was dissociation-alcoholism in its most hideous form. It was impossible to discuss the alcohol problem without recognizing its moral implications, and psychology made it necessary to take account of these. If it was true that alcoholism was in the main a disorder of the mind it must be dealt with by the best psychological methods. To attempt to kill the craving for alcohol by enforced confinement could only result in the regressions of Freud or the law of reversed effort of Coné and Baudouin. For his own part, he believed the greatest hope to be in the practice of auto-suggestion, but whatever method was adopted must depend upon the recognition of the psychological aspect of alcoholism.

Mr. THEODORE NEILD, M.A., felt, as a layman, that further information as to the action of alcohol on the body was needed. It was stated that only a definite quantity could be oxidized in unit time by a man of given size at rest, and that it was only with low concentrations that exercise increased the combustion of alcohol. Stronger concentrations seemed so to affect the cells of the body as to reduce the combustion to the low concentration order, and Atwater and Benedict set down only 2 per cent. as secreted. Where did the large balance, beyond the 180 c.cm. or so that could apparently be oxidized, go to? Professor Mellanby, in the Special Report (No. 31) of the Medical Research Council, remarked that with low concentrations it appeared as if some demand were first made on the small quantity of alcohol by some other tissues before the blood received its portion. Was it possible that some such tissue absorption might account for the mysterious disappearance of the balance of heavy quantities of alcohol drunk by some persons? The speaker further asked whether the experiments of Atwater and Benedict had not governed us long enough. The experiments were criticized when they appeared by Professor Gowland Hopkins, and the

late Sir G. S. Woodhead had told him that he greatly desired to repeat them. Was it not possible now to repeat those experiments?

Professor W. E. Dixon (Cambridge) was convinced that a discussion such as that could lead to no useful purpose. As Professor Cusny had referred to some experiments by Dr. Rivers, perhaps as he (the speaker) was associated with Rivers in these experiments he might say a few words. Rivers measured the amount of work which men were able to perform, and did it in a very accurate manner; then he gave these men a certain quantity of alcohol and again measured their work. The work always increased under this stimulus. It looked as if, having got his “drop,” the man set about to do his very best. But the man had to be given his alcohol every day—sometimes the alcohol was carefully masked—and it was found that the amount of alcohol had to be increased before it had any effect on increasing the output. To the man who had been taking alcohol, 20 c.cm., properly diluted, had no effect in increasing the work; it was not until he increased the potion to 40 c.cm. that the amount of work was increased.

Sir JAMES BARR (Liverpool) congratulated Professor Mellanby on a very able and temperate paper. The advantages of alcohol were not very obvious, and to the person who did not take alcohol it was very difficult to realize any advantages at all. While praising the temperate character of Professor Mellanby's paper, he thought that the doses given in his experiments were intemperate. Mellanby talked of giving 7 or 10 c.cm. of alcohol every hour. In whisky 10 c.cm. was equivalent to about 1½ oz., and in 5 per cent. beer to about 7 oz., and a man who drank a glass of beer every hour of the day would not be in a fit condition for doing much. He did not think there was much use for alcohol in the pharmacopoeia. It was more as a beverage from the social point of view that alcohol should be regarded. He attributed a large amount of the present-day unrest to the expensiveness of alcohol, and added that the murderers and cut-throats in Ireland, Russia, and elsewhere were very largely teetotallers. He would be sorry to see the moderate use of alcohol abolished in this country.

Dr. JAMES CHALMERS (Sunderland) said that as a student he was taught that alcohol, well diluted and taken only with food, assisted digestion. As a medical practitioner of thirty years' standing he saw no great reason to depart from that conclusion. He himself, however, was a total abstainer, in the first place because it required all the wits he could summon to carry on his professional work without any mental handicap from indulgence in alcohol; secondly, because alcohol weakened the will, and if a man began to use it he did not know where he was going to stop; and, thirdly, because an abstainer was free from many degenerative changes from which alcoholics suffered, and if he did have any disease he had a better chance of recovery than the alcohol-consuming person, and the recovery was more complete. At the same time a little alcohol, well diluted, was a valuable adjunct to the treatment of pneumonia and enteric fever.

ALCOHOL IN ITS RELATION TO THE PROBLEMS OF MENTAL DISORDERS.

BY

Sir FREDERICK W. MOTT, K.B.E., M.D., LL.D., F.R.S.

I PROPOSE to discuss the subject of alcohol in relation to mental disorders under three headings, according to my experiences, first, as a member of the Scientific Committee of the Liquor Control Board; secondly, as Physician to Charing Cross Hospital and Pathologist to the London County Asylums; and thirdly, as a neurological expert in the army during the war.

PART I.

The Physiological Action of Alcohol on the Nervous System.

The main effects of alcohol that have any real significance are upon the nervous system. The action of alcohol on the nervous system is essentially sedative, and, with the possible exception of its direct influence on the respiratory centre, is not truly stimulant. The apparent stimulant effects are due to the narcotic effects of alcohol on the highest controlling

ntres of the organ of mind, leading to a release from control the evolutionary lower centres.

"The emotional dispositions or capacities of man are of very icient racial endowment, and have their physiological calization in the basal ganglia, the lowest levels of the eat brain, the parts which are alone represented in the west vertebrates. The higher intellectual faculties, on o other hand, are the latest acquired and are connected ith the anatomically latest developed parts of the brain. rmediate between these come, in the order of develop- ent, the sensory and skilled motor functions and their nervo ntrous."

Proportional to the degree of concentration of alcohol in e blood, and thereby in the cerebro-spinal fluid, is the effect i depression or suspension of the functions of the various olutional levels in the inverse order of their phylogenetic ad ontogenetic development. The last to come evolutionally, herefore the least stable and firmly organized, is the first to o. This highest functional psychic level, which is so varied i capacity in different individuals, has developed *pari passu* ith progressive evolution of the social instinct. Now the elings of a civilized human being are largely dominated, and is behaviour determined, by the customs, traditions, religion, nd social usages of the community and race. Experience ows that disorders of conduct arising from the effects of colchol—and in speaking of disorders of conduct I refer to all rms of antisocial conduct, whether it be crime or insanity— e dependent not only upon the quantity of alcohol consumed, nd the period over which inebriety extends, but even more pon the inborn degree of organization and stability of this highest psychic level.

Evolutional Levels of Hughlings Jackson in Relation to the Effects of Alcohol.

Hughlings Jackson, in his philosophic paper on the factors f insanities, pointed out that the different depths of dissolution of the evolutionary levels, and the positive and negative phases of symptoms arising as a result of successive dissolution of these levels, constituted a basis for the study of insanities. Maudsley has stated, "A drunken man notably exhibits the abstract and brief chronicle of insanity, going through its successive phases in a short space of time." Lot is see how far those views accord with the facts.

Alcohol affects as a narcotic the synaptic junctions of all the neurones, but it affects first the synapses of this highest evolutionary level, causing at first hypofunction, and later loss of function. The effects are not stimulant on this level, out sedative and narcotic; alcohol thus releases from control the lower levels, thereby permitting a positive phase in the lower levels—for example, a brisk flow of ideans translated into speech and action associated with self-confidence. There is, however, a diminution of self-criticism, deliberation, and judgement when this level is narcotized by alcohol; and this psychic level being inherently of a deficient organization and stability, a small quantity is sufficient to produce this effect. Experiments show that alcohol taken under conditions of restful environment and mental placidity—that is, where there is no external or internal exciting cause—has a sedative effect, and leads to drowsiness and sleep. Consequently, the apparent stimulating effects are due to the narcotic action on the highest psychic level and release of control over the lower levels, which are thereby much more easily roused by internal or external stimulation to activity.

As alcohol concentrates in the blood the second depth of dissolution occurs. This is a progressive falling off of awareness and self-criticism, which is manifested by excited talk, aggressiveness, and inflamed emotions, accompanied by fine sensory-motor disturbances as exhibited in difficulties of articulate speech, diminished acuity of aesthetic sense perceptions, and more or less clumsiness in the execution of fine skilled movements.

In the third stage of dissolution the negative condition of the higher functions of the organ of mind is very great. There is manifest evidence now of affection of lower levels by coarse sensory-motor disorders—for example, double vision, motor inco-ordination, instability of gait and station, incoherent ideans in conversation; on the emotional side the individual is either expansive and quarrelsome, or melancholic and maudlin, the *vin gai* and *vin triste* of the French, and the drunk and disorderly of our police courts.

In the fourth stage of dissolution there is a total dementia and stupor with stertorous breathing, and often incontinence of urine and faeces. Gradually these conditions pass over into

a state of deep sleep, after which the patient usually returns to the normal condition. In some cases, however, when the quantity of alcohol taken is very large, the vital centres are so greatly affected that the drunkard may become comatose and die of failure of respiration. It is generally estimated that when the blood content is 0.6 per cent. of alcohol, which amounts to about 14 oz. of absolute alcohol, or nearly a pint and a half of proof spirit, there is a considerable likelihood of death ensuing. The quantity of beer which would contain this amount of alcohol would be over two gallons, so that it is easy to understand that a concentration in the blood sufficient to kill is not so likely to occur with beer as with spirits.

Tolerance to Alcohol of the Habitual Drunkard.

As a result of continued use, tolerance can be acquired, so that the habitual drunkard may consume, without becoming intoxicated, quantities of alcoholic beverages which would cause well-marked signs of drunkenness, or even prove fatal to the person not accustomed to it. The acquisition of tolerance, however, implies a removal of a protective mechanism, for it allows the drunkard to imbibe daily quantities of alcohol which he could not have taken if his brain had retained its normal power of reacting to it; eventually he becomes a chronic inebriate, and develops sooner or later pathological conditions.

PART II.

I will now pass on to my experiences as Physician to Charing Cross Hospital and Pathologist to the London County Asylums. These were the subject of a report to the International Congress of Psychiatry held in Amsterdam in 1907.

Unreliability of Asylum Statistics in Relation to the Influence of Alcohol in the Production of Insanity.

The statistics relating to alcohol and insanity in the London County Asylums (for thirteen years) show that the percentages of admissions in which alcohol was the asserted cause of insanity varied considerably in different asylums in the same years and in the same asylum for different years, and the differences were so great that the collected statistics derived from this source are not reliable. The personal equation of the medical officers who obtained the information and the friends who gave it, as to what constitutes alcoholic excess, and as to how far alcohol is an efficient cause, or merely a coefficient in the production of insanity, was variable. Thus in one year, 1902, from the same class of people, alcohol is the assigned cause of 25.6 per cent. of the admissions to Hanwell, and to Claybury 11.2 per cent.; but in 1906, in 28 per cent. of the admissions to Claybury intemperance is the assigned cause, while at Colney Hatch it is only 14 per cent. At Bexley, where the statistics appeared to be fairly uniform since its opening, intemperance as an assigned cause was high, the average being 22.8 per cent. for the seven years; but an analysis of the cases admitted during 1905 to this asylum, in which intemperance was the assigned cause in 25.7 per cent. of the total admissions, shows that there were many in which other causes were associated. Thus, out of 248 male admissions, alcoholic excess was the assigned cause in 46, or 18.5 per cent., and out of 246 female admissions alcoholic excess was the principal cause in 33, or 15.4 per cent.—a total percentage on the whole admissions of 17 per cent. But when we inquire into these cases, we find that 13 were imbeciles, 5 were cases of chronic delusional insanity, 5 were epileptic, 5 had organic dementia, and no less than 20 were cases of primary dementia. In fact, out of the 84 cases quite one-half were lunatics or potential lunatics and the subjects of an inborn tendency to mental disease. My experience at Hanwell, Claybury, and the other asylums I visited corroborated this statement.

The Histories in the great Majority of Cases in which Alcohol was an Assigned Cause show an Inborn or Acquired Intolerance.

I have found that the notes show hereditary insanity or epilepsy quite as frequently in these so-called alcoholic cases as in other forms of insanity, and more frequently than in general paralysis. In the histories of these cases of insanity as a result of intemperance we find frequently potential insanity, chronic alcoholism in one or both parents, inherent instability in the form of neuropathics, imbecility, criminal degeneracy, epilepsy, and intolerance of alcohol as manifested by previous admissions, when they were termed recurrent mania, recurrent melancholia, sometimes head injury, brain

disease, or incipient general paralysis. Suicidal tendency and active attempts at suicide, occasionally murderous assaults or homicidal tendencies, indecent assaults upon children, rape and other sexual crimes are occasionally met with in the histories. Again, the history frequently reveals that the patient has taken to drink on account of domestic troubles, bodily illness, loss of money, breaking up of the home, and all those conditions of life in which alcohol is at first taken to obtain temporary relief by those who are burdened with sorrow and despair, the ill-fed and miserable, subjects of mental and bodily suffering. Those, again, who, owing to a suspicious or melancholic inborn temperament, can persevere only see the black side of life, who are potentially insane, under the toxic influence of alcohol develop hallucinations and delusions of a persecutory character.

Polynuritic or Korsakoff Psychosis, the Type of Insanity in which Alcohol is the Essential Cause.

The types of insanity in which alcohol is the essential cause are not nearly so frequently seen in asylums as is generally supposed; they differ but little from the cases met with in hospitals. They are delirium tremens, mania a potu, and polynuritic psychosis, or Korsakoff's disease, which is generally regarded as a form of chronic delirium tremens, and affects women more frequently than men. Doubtless a considerable number of pure alcoholic cases are kept in the infirmaries, and only those in which the mental symptoms are pronounced and prolonged are sent to the asylums. We may thus divide the cases of alcoholic insanity met with in asylums into two great groups:

I. Those with intolerance to alcohol, owing to a *locus minoris resistentiae* in the nervous system, especially of the highest evolutionary level. These cases are the most numerous.

II. Those in which chronic alcoholism, usually in conjunction with some other factor, such as syphilis, tuberculosis, microbial toxæmia, arterio-sclerosis, head injury, or organic brain disease, induces sooner or later either delirium tremens, polynuritic psychosis, or alcoholic hallucinosis.

Consequently, cases belonging to Class I can very seldom drink sufficient alcohol extended over a sufficient time to produce advanced cirrhosis of the liver with ascites. A good many may drink sufficient to produce changes in the liver discoverable by microscopical examination, but very few sufficient to produce a change recognizable by the naked eye.

Class II, however, includes cases of alcoholism affecting persons of an inborn stable mental organization as a rule; consequently it is in such cases especially that we find the few cases of large, fatty, and cirrhotic liver on the *post-mortem* tables of asylums.

Statistics of Post-mortem Examinations in Hospitals and Asylums Compared.

II, now, we compare the statistics of hospital and asylum *post-mortem* examinations we are struck with the fact that in the former there are a large number of cases of advanced cirrhosis of the liver, whereas in the latter there are relatively few, and many of those only recognizable with difficulty. I will throw on the screen a statistical analysis of the results obtained in 1,099 autopsies on adults at Charing Cross Hospital, compared with 1,271 *post-mortem* examinations at Claybury. An analysis of the results obtained by Sir Humphry Rolleston and Dr. Fenton on *post-mortem* records extending over ten years at St. George's Hospital is given, and in the main it supports the opinion that the statistics derived from Charing Cross Hospital agree with those which could be obtained at other London hospitals.

The principal points of interest which this tabular synopsis of a comparative inquiry into the *post-mortem* incidence of cirrhosis of the liver at Charing Cross Hospital and Claybury Asylum afford in relation to the subject of alcohol and insanity may be thus summarized:

At Charing Cross Hospital the notes of the autopsies upon 1,099 adult cases were examined—735 males and 364 females. Of this number there were 85, or 7.7 per cent., cases of cirrhosis of the liver, which accords closely with the 8 per cent. in which alcohol was the immediate and direct cause of the disease for which patients were admitted to the hospital. The percentage of males was 9.1, and of females 4.9.

At Claybury Asylum the notes of 1,271 autopsies were investigated (627 males and 644 females). Of this number only 23 cases of hepatic cirrhosis were found (14 males and 9 females). The total percentage of cirrhosis of the liver works out at 1.8 per cent. (males 2.2 per cent. and females 1.3 per cent.).

There are a number of points of interest to which the synopsis refers, but I will limit my remarks thereon to the following more important facts which have been elucidated—namely, that no case of cirrhosis with ascites occurred at Claybury Asylum, whereas of the cases of cirrhosis at Charing Cross Hospital 66.6 per cent. had ascites, 22.2 per cent. with a history of paracentesis abdominis. At Claybury, in only one instance of the 23 cases was cirrhosis of the liver mentioned as the assigned cause of death, whereas at the hospital in 72.2 per cent. of the 85 cases cirrhosis of the liver was assigned as the cause of death. The cases of cirrhosis of the liver met with on the *post-mortem* table at the asylum were mostly cases of polynuritic psychosis and alcoholic dementia, but there were also a few cases of general paralysis. The single case in which cirrhosis of the liver was the cause of death occurred in a chronic alcoholic billiard-marker, who was admitted to the asylum because he had attempted suicide. This man had previously given himself up to the police as having murdered a woman, which was a delusion. When in the asylum he knew that he suffered with cirrhosis of the liver, and he stated that he felt so miserable on this account that he had attempted suicide. The liver weighed over 2,000 grams. The relatively greater frequency with which acute and chronic gastritis and other inflammatory lesions of the stomach are met with in cases of alcoholic affections of the liver among the insane is shown.

There is a greater frequency of arterio-sclerotic changes associated with cirrhosis of the liver in the case of the insane, especially among the males. Atheroma and pearly fibrosis of the aorta is common on the *post-mortem* table, even in comparatively young people, in asylums. Probably this is explained by the fact that a large proportion of the deaths occur in the subjects of general paralysis, due to the syphilitic origin, acquired or congenital, of this disease.

It may be remarked that in only four of the fatal cases occurring at the hospital were there nervous symptoms associated. In fact, it is noteworthy that alcoholic cirrhosis of the liver with pronounced ascites and a history of prolonged intemperance, even excessive intemperance, frequently occurs in individuals who show absolutely no mental symptoms beyond a weakened will and loss of moral sense, shown by the indulgence of a vicious habit.

Regional Dissociation between Alcoholism and Insanity.

I would therefore agree with Dr. Sullivan¹ and Dr. Bevan Lewis² that alcohol as an efficient cause of insanity is not so great as the published reports of the Lunacy Commissioners indicate. In support of this I will briefly indicate some of their arguments. Dr. Bevan Lewis has shown a regional dissociation between alcoholism and insanity. Thus inland and agricultural communities were the least inebriate, but had the highest ratio of pauperism and insanity; while maritime, mining, and manufacturing communities above all others were the most intemperate, and revealed the lowest ratios of pauperism and insanity. Dr. Sullivan, by careful analysis and tables, shows conclusively that in the regional distribution of insanity it is difficult to trace any evidence of alcoholic influence such as might be expected if alcoholism really accounted for a sixth of the total number of cases. Thus Lancashire, Warwick, and Cheshire, which rank very high in the scale of alcoholism, and the mining counties, where drunkenness is very rife, are alike in showing very low rates of insanity. He concludes that alcohol, as the essential cause of certified insanity, falls a good deal short of the 16 per cent. at which it is rated in the official statistics, and may possibly be something under 10 per cent.

Intolerance of Alcohol in Mental Defectives.

Dr. Branthwaite, in his Report of 1905 concerning certified inebriate reformatories established under the Inebriates Acts, 1879, 1900 (p. 10), remarks:

"Upwards of 62 per cent. of the persons committed to reformatories under the Act are found to be insane or defective in varying degree. I am satisfied that the majority of our insane inebriates have become alcoholic because of congenital defects or tendency to insanity, not insane as the result of alcoholism, and that the drunkenness which preceded alcoholic insanity was merely the herald—the only obvious sign—of incipient mental disorder. In relation to the final insanity, drunkenness in such cases is the intensifier perhaps, but not the cause of the disease."

Concerning the congenital defectives, who are divided into two classes—(a) comprising degenerates, imbeciles, and epileptics, and (b) moral and social defectives—he remarks:

"A marked intolerance to the action of alcohol is present in both refractory and quiet class of defectives, very small quantities of

drink, no more than is taken daily without apparent physiological effect by an ordinary individual, being sufficient to cause disorderly and violent behaviour. Our experience in this direction has led us to accept the view that intolerance to the exciting effects of small quantities of alcohol may be considered a fairly certain sign of impaired mental equilibrium."

I think I have given sufficient evidence to show that the effects of alcohol depend not only upon the quality and quantity taken but also upon the personality of the individual who takes it.

The Different Pathological Effects of Alcohol upon Different Individuals.

We are prepared now to understand how very different is the effect of alcohol on different individuals. Let us consider first the well-fed workman, business or professional man of normal mental stability, who on account of his occupation becomes the victim of a vicious habit of indulgence in alcohol to excess. The normal sense of well-being in such an individual which comes from physiological nutritional equilibrium is gradually perverted and replaced by an artificial sense of well-being, owing to the effect of the alcohol. Sooner or later visceral disturbances—notably gastritis—lead to loss of appetite and failing nutrition, with more or less persistent disorder of his organic sensibility. The craving for spirits replaces the desire for food, and the vicious habit has so altered his nervous system that it can no longer function without stimulant. For a time the symptoms of disordered organic sensibility due to chronic alcoholism—namely, pain and oppression in the region of the heart, dyspepsia, anorexia, nausea, and morning vomiting, muscular weakness and tremors—may be relieved by alcohol, but the quantity taken has to be steadily increased to produce the desired effect. A head injury, microbial infection, an extra bout of drinking, and the sudden withdrawal of the alcohol, may lead to delirium tremens, when the drinker becomes dangerous to himself and others. Such subjects of chronic alcoholism may live until advanced cirrhosis of the liver with ascites occurs, from which they eventually die after repeated operations for paracentesis. It may be presumed that they possessed an inborn stable mental organization, and, without having any precise statistical data to prove it, I am of opinion that they would transmit to progeny the stable mental organization they inherited rather than the weakened will power which they had acquired by force of circumstance of environment.

The frequency with which crimes of violence, murderous assaults, and homicide occur as the result of chronic alcoholism indicates that, owing to the loss of control, the natural emotion anger, with its derived sentiment courage, are converted into fury and recklessness. Again, the frequency with which suicide occurs as a result of chronic alcoholism indicates that the normal sentiment of sorrow becomes despair owing to degradation and inability to struggle against adversity. The sentiments of joy and sorrow are strikingly exhibited by the effect of alcohol on two opposite temperaments, and the French speak of the *vin gai* and the *vin triste* types of drunkenness. The narcotic effect of the alcohol on the evolutionally highest psychic level in the chronic inebriate permanently weakens self-criticism, and leads him to become the subject of a vicious habit over which he has no control. Then an extra bout of drinking may lead to criminal actions; such a person, however, is not deemed insane.

Again, chronic alcoholics are very liable to sexual crimes, rape, and indecent assault, also to exhibitionism, assaults on children, and various sexual perversions. According to Dr. Sullivan (*Alcoholism*, p. 164):

"Prison statistics indicate that 60 per cent. of graver homicidal offences and 82 per cent. of assaults are attributable to alcohol, and that in nearly all the cases of the former class and in four-fifths of the minor offences the intoxication had attained a fair degree of chronicity."

To a less degree sexual crimes are committed by alcoholism. Thus we know that a chronic alcoholic is more antisocial although uncertainable than a certifiable lunatic. The release of highest control inflames the emotions, and it is not surprising, therefore, to find that alcoholism is responsible for a large proportion of the crimes of violence.

It may be asked, How is it that many of these chronic alcoholics in all stations of life are such good skilled workmen and artists? Because individual character also results from one or several inherited tendencies, and the master intellectual feeling—that with which his whole nature is

imbued, and the actions of which have by conscious repetition become *subconscious and habitual*—may persist when other feelings have become perverted and gone. Even the *aesthetic feeling*, which is the last to come evolutionally, therefore normally the first to go, may, owing to its constant, habitual, and subconscious activities in associative memory, tolerate better the degrading effects of chronic alcoholism and resist longer the work of destruction than the moral sense; even the elementary feelings of right and wrong may be lost or perverted and the aesthetic sense remain. Thus a chronic alcoholic artist may by his conduct be antisocial and yet still delight the public by his art, whether it be painting, sculpture, music, poetry, or the drama. It is sometimes brought forward as an argument in favour of the use of alcohol that some of the greatest artistic geniuses have used it even to excess. It is assumed that it has stimulated their emotions and imaginative faculties, even if it weakened their will power, and having made them indifferent to social customs, their aesthetic feelings and passions were given full play without restraint. But "poets are born, not made," and their poetic imagination persists in spite of alcohol.

Chronic alcoholism may be manifested in the patient's conversation in various ways. There is often a remarkable tendency to wit and humour, but not infrequently the mental association is rather by rhyme and repetition of well-worn jokes, abusive epithets, and coarse, vulgar stories, with occasionally keen repartee and warm-heartedness. Again, boastful loquacity, untruthfulness, loss of power of attention, and the tendency to relate pseudo-remembrances, is a common symptom of chronic alcoholism (the character of Falstaff).

Alcoholic Insanity.

Both in hospital and asylum practice delirium tremens is much more frequent in males than in females; whereas polymenitic psychosis is much more frequently met with in females than in males. Both occur in the subjects of chronic alcoholism. Women often take to drink because of the pains experienced at the menstrual periods, and on account of disease of the reproductive organs following miscarriages, abortion, and venereal infection. I have, moreover, so often found, *post mortem*, metritis, parametritis, and salpingitis in cases of alcoholic paraplegia, that I have thought it probable that the toxins engendered by microbial infection, carried up the lymphatics of the nerves, have exercised an important causal relationship to the polynouritis.

As a rule the convolitional pattern of the brain in these cases of polynouritic psychosis denotes a fair order of intelligence, and the wasting of the convolutions and the thickening of the membranes is slight as compared with that occurring in general paralysis.

There is a form of alcoholic dementia of the expansive form that simulates general paralysis. The patient may suffer with delusions of grandeur associated with some evidence of neuritis, but a diagnosis can always be made by an examination of the cerebro-spinal fluid.

The changes in the brain in alcoholic dementia are not marked as a rule, and do not, in my opinion, account for the symptoms as they do in general paralysis, where the dementia is in great measure proportional to the cortical destruction.

The great proportion of cases which are statistically included under alcoholic insanity occur in persons of an inborn or acquired unstable mental organization—epileptics, degenerates, imbeciles, potential lunatics, general paralytics, subjects of head injury, local brain disease, syphilis, and arterio-sclerosis.

If alcohol is the essential factor, however, in the production of an insanity, there will be certain specific indications in the varied forms of insanity pointing to the more or less specific action of the alcohol. Even in the absence of a history of alcoholic indulgence there are certain physical signs and symptoms which point to alcohol as the cause. The more definite these signs and symptoms the more certain can we be that the cause is removable and the more hopeful the prognosis. These signs and symptoms are found most pronounced in the two conditions of mental and nervous disorder which occur in hospital practice—namely, delirium tremens and polynouritic psychosis.

Polynouritic Psychosis—Korsakoff's Disease.

Although every form of mental derangement may be closely simulated by alcohol when an insane temperament is acted

upon by a sufficient quantity of the poison, yet when alcohol has been an efficient cause in the production of the insanity there are certain indications in the character and constancy of the illusions, hallucinations, and delusions. Illusions of identification of persons are common. The hallucinations and delusions are generally of a persecutory nature, and are possibly due to a deranged and perverted organic sensibility of the body and viscera. In one case a woman with poly-neuritic psychosis said her body was on fire and she tried to get out of the window. The next day blebs occurred on the body, and I found acute degeneration of the nerves going to these patches of skin. Often the woman fancies she hears the baby crying and that it is in the bed. Delusions of marital infidelity are especially common in men and may lead to homicidal assaults. Loss of orientation in time and space and of memory of recent events is usually met with, likewise a tendency to pseudo-rominiscences and mental confusion, which in some cases amounts to incoherence, and may then overshadow completely the disturbance of memory. Purposeful motor restlessness, hallucinations, and delusions are common, and tremors of the tongue and the small muscles of the face. Moreover, alteration of the deep reflexes, tenderness on deep pressure of the muscles, anaesthesia, paraesthesia, hyperaesthesia—indicative of neuritic affection—are frequently present, singly or combined.

Alcoholic Hallucinoses.

The cases of alcoholic hallucinosis may, however, show very little or no mental confusion and amnesia, and hardly any loss of orientation. They tend to recover within one to six months after admission, but relapses are frequent. Since auditory and visual hallucinations, especially the former, frequently occur in insanity in which there is no alcoholic factor, it is often difficult to decide simply, by the hallucinations and delusions alone whether alcohol is the cause. Should they persist, however, while the mind otherwise becomes clear, it is highly probable that the case is one in which alcohol has only played a subordinate part, and the outlook of recurrent or chronic insanity is probable. This is all the more likely to be so if the hallucinations and delusions become systematized and if there is a complete absence of any peripheral cause.

Dipsomania.

A periodic form of alcoholic insanity, akin to recurrent mania, is met with, termed "dipsomania." Persons who in the intervals are decent sober members of society, leading, perhaps, a blameless life with no intellectual or moral defects, are seized with a craving for drink. Often long periods of normal conduct occur between periods of debauch, in which they go on drinking day after day, taking little food and getting little sleep, until exhaustion from want of food sets in, and, tremulous and miserable, the craving being at last satiated, they return to their home and occupation until another attack occurs. There is usually a morbid nervous inheritance in these cases, and it is regarded by many authorities as a form of manic-depressive insanity.

Alcohol and Syphilis.

Here I would call attention to the effects of alcohol in the spread of venereal disease. Syphilis is so often acquired as a consequence of alcoholic intoxication that the effects of the contagion are frequently attributed to the alcohol.

PART III.

Alcohol and War Neuroses and Psychoses.

An inquiry which I made regarding the influence of alcohol in the production of war neuroses and the value of the rum ration was of interest in relation to the inborn temperament and alcohol. By a card system I found that at least 60 per cent. of 147 cases which were admitted under my care to the Maudsley Neurological Section of the 4th London General Hospital in 1917 were total abstainers, which was double the percentage of 62 cases admitted to Ruskin Park Hospital suffering with wounds or diseases other than functional nervous conditions.

The high percentage of total abstainers among cases of war neurosis and shell shock was associated with fear of the consequences of drink, or a dislike of the taste of drink, consequently refusal to take the rum ration. Fear of the consequences, in a great number of instances, was due to the results in the home of paternal drunkenness, and in fewer

instances of maternal drunkenness, or drunkenness in both parents.

It was observed that a number of total abstainers admitted that the rum ration had been beneficial, and that they had taken it when they had to "stand to" in the trenches wet and cold in the early morning, prior to getting over the parapet for an attack.

Moreover, I questioned a number of officers of all ranks, even including advocates of temperance, and with very few exceptions they were convinced of the value of the rum ration if it were given out by an officer who saw that no soldier obtained more than his ration. They emphasized its utility as a stimulant when the men were wet and cold and had to stand to at dawn; it put the feeling of warmth in them, and gave them the necessary stimulus and ardour to go over the parapet for an attack. The general recommendation was to give it in the tea, and the men preferred it so; only a few cared for it neat—it was too strong. Many officers and men were of opinion that on returning to billets, cold and wet through, a rum ration produced a comforting feeling and promoted sleep.

It was the almost unanimous opinion of the witnesses who gave evidence before the Shell Shock Commission that the rum ration given under the conditions above mentioned was most useful, and the conclusions of the Advisory Committee of the Central Control Board (Liquor Traffic) was as follows:

"Alcohol, its Action on the Human Organism.—The main effects of alcohol that have any real significance are due to its action on the nervous system. So far as direct action is concerned, alcohol, when administered in moderate doses in dilute form and with sufficient intervals, has no effect of any serious and practical account. The action of alcohol is not really a stimulant to the nervous system, but a sedative to the highest centres of control, and acts by causing a decrease of critical self-consciousness and anxiety.

"When stimulation of nervous function is really needed, and when the individual has to meet an emergency which calls for the exercise of his highest powers of perception and judgement, alcohol is not merely useless—it is certainly and unequivocally detrimental. On the other hand, there are emergencies when, though the individual may also imagine that he needs to be braced up nervously, he would be assisted far more by a relaxation than by an increase of tension; and here the sedative action of alcohol, so far as the immediate effect is concerned, may be advantageous. The value widely attributed to the rum ration, under the conditions of acute discomfort, cold, and strain inseparable from trench warfare, may be explained in this way."

Captain J. M. Wolfsohn,¹ of the American Army Medical Service, at my suggestion investigated the personal history and the leading nervous state in 100 of my cases of soldiers suffering with shell shock or war psychoneuroses (neurasthenia and hysteria) and compared the same with 100 surgical cases suffering with wounds under the care of Captain Turner at the 4th London General Hospital, and found that the vast majority of the psychoneurotic cases studied were among soldiers who had a neuropathic soil. In 74 per cent. of these cases a family history of neurotic or psychotic stigmata, including insanity, epilepsy, alcoholism, and nervousness was obtained, whilst a previous neuropathic constitution in the patient himself was present in 72 per cent.—a striking contrast to the percentages obtained in the wounded cases.

Finally, a quantity insufficient to affect the normal human being is enough to render the individual with an invalid brain antisocial; consequently cases of shell shock, mental deficiency, neurasthenia, epilepsy, and head injury are very susceptible to the toxic effects of alcohol. According to the experience of Major Hotchkiss at Dykebar Asylum, between cases of delirium tremens and the chronic delusional form of alcoholic insanity are those cases which show such varied symptoms as mental confusion, depression, subacute excitement, and in practically all cases hallucinations.

"The history of many of these cases suggested that though alcoholism was a prominent feature in predisposing to a mental breakdown, of still greater importance was the stress and strain of the campaign, and had it not been for this, breakdown would never have occurred or would have been postponed."

Probably the family history in many of these cases of alcoholic hallucinosis would show an inborn neuropathic tendency.

GENERAL ETIOLOGICAL FACTORS IN THE
ALCOHOLIC PSYCHOSES.

BY

JOHN T. MACCURDY, M.D.,

Cornell University Medical College, New York.

WHEN I was honoured with an invitation to read a paper to this important gathering on the subject of alcohol in relation to mental disease, my first thought was that, as an American psychiatrist, I would be expected to discuss the effects of prohibition on the incidence of insanity. Unfortunately the time was too short to allow of my getting the latest statistics on the subject, as that would involve considerable correspondence back and forth. Then it occurred to me that if I had the statistics I would feel it a most unsafe thing to draw any conclusions from them, and that you might be interested in having a discussion of aspects of the alcohol problem which social reformers and many medical men are apt to overlook.

When I express scepticism as to the reliability of current statistics I would not have you assume that I refer to the alleged failure of prohibition to prohibit, which is so much advertised in this country. No one imagined when the constitutional amendment was passed that all alcohol would spontaneously evaporate. Even enthusiastic reformers knew that certain sections of the population would endeavour to evade the law and often succeed; moreover, the possession of liquor was not banned, and those who wished and had the money were in a position to fill their cellars before the law was enforced. Further, one must remember that drinking in the home is not illegal. So, if a guest from this country be given a cocktail before dinner by his host, he has no right to assume that any law has been broken. Nevertheless it would be foolish to claim that there is no illicit traffic. Public opinion—if one can gauge that by the verdicts of juries—is ready to back up prosecution of those who import and sell alcoholic beverages for gain. It is not so antagonistic to their domestic manufacture. In consequence there are two sources for post-prohibition liquor, and these involve radical modifications in the type of drinking. "Boot-legging"—that is, illicit traffic in alcohol—means expensive liquor which must be concentrated to make it pay. Those who buy must therefore have money to spare and are often apt to consume what they can get more greedily than if future supply were assured. Further, the quality of what is secured in this unlicensed manner is not guaranteed. On the other hand the drinks most easily made in the home are beer and light wines. Those who demand alcohol and are not in a position to buy are reduced to beverages of low percentage. Some people with sufficient technical skill distil at home, and these are apt to consume raw and highly poisonous spirit. Above all, it must be borne in mind that the saloon, in the sense of a place where a man could stroll casually in to take one drink, be treated, stand treat, and eventually leave dead drunk—the saloon has disappeared, and in all probability for good.

We see, then, that drinking has changed both in quantity and quality. The rich man has good wines and spirits from pre-prohibition days or may buy stuff of indifferent quality. The poor man no longer has spirits, but can, if he takes the trouble, drink wines and beer. There is, probably, much less alcohol consumed now than there was. Even if more inebriety be observed in certain social sets there are fewer drunken people in the streets and hospitals. But, if one is to draw conclusions, one way or another, from the state of affairs now existing he would be liable to error, for the change in type of drinking is in progress. The evolution is not complete. The excitement of smuggling will certainly abate in time; social emulation as an incentive for the procuring of liquor may either be fixed as custom or entirely pass away. Domestic manufacture of mild alcoholic drinks may develop into a recognized household art, be legalized, and produce a nation of moderate drinkers. These are fields for pure speculation, and I have mentioned them only to indicate the folly of trying to draw conclusions of any permanent value from conditions obtaining in America to-day.

There is another factor which may tend to vitiate current psychiatric statistics. We have not yet finished with the war. This social upheaval tends both to increase and decrease the present incidence of insanity. Certain factors, such as

the economic unrest and the violent changes in moral and social outlook, inevitably make difficult the maintenance of balance in the mentally unstable. On the other hand, the high proportion of insanity in military life may tend to reduce its incidence some years thereafter. In the American army, at least, the number of definite psychotic breakdowns has always been higher than in the same age group in the civilian population. When these patients are examined it is found that they had, many of them, typical dementia praecox personalities. It is not impossible that frank psychoses would inevitably have occurred anyway, and that the strain of adaptation to rigorously disciplined life merely brought them on earlier. In that case one would now expect a lower rate of chronic mental disease of the constitutional type since so many candidates have already met their fate. One could go on indefinitely with such arguments, always reaching the same conclusion: that we can infer nothing of permanent value from the contemporary insanity rate.

But this is not my theme to-day, which is rather consideration of the factors that always operate to confuse the study of alcoholic psychoses. The problem may be approached from two sides, although the same phenomena often seem of equal importance when viewed from the two angles. The first question is of the psychological need for excessive potation and the other is of the causes operating to produce the symptoms of so-called alcoholic psychoses. By discussing the latter first, we may from a study of the effects produced by alcohol deduce something which may throw light on the reasons for its consumption.

The simplest of all mental disturbances ascribed to alcohol is delirium tremens. Here we have a group of symptoms all of which point towards an acute intoxication of the central and involuntary nervous systems. It is not necessary to recapitulate these symptoms before this audience. It will be sufficient to point out that the mental aberrations take the form of clouding of consciousness, with disorientation, etc., and hallucinations. The latter are, in uncomplicated cases, usually of small moving objects; quite possibly these are false interpretations of entoptic phenomena. At any rate all the psychotic features are of a kind we are accustomed to speak of as "organic" rather than "functional." Functional symptoms are "psychogenic"—that is, they may be demonstrated to have a psychic history, to be products of the instinctive or emotional conflicts of the patient. For instance, if a thwarted ambition reaches fulfilment in a delusion we speak of this imagination as psychogenic or functional. Nothing of this kind may appear in delirium tremens, although the bizarre hallucinations which sometimes occur may have a symbolic significance suggestive of previous unconscious elaboration. On the other hand all the obvious symptoms point to an acute poisoning of the nervous systems. Some toxin is directly injuring the machine rather than there being a perversion of the forces which operate it.

Another condition in which the mechanism of the brain seems to be directly affected is that rarer state known as the Korsakoff syndrome. Here we have a sudden onset of delirium with polyneuritis. This delirium is of a definitely organic order with clouding of consciousness and occupational hallucinations. As it clears up the patient is left with a peculiar memory defect in which he cannot properly register or recall current impressions. This last symptom is, of course, of a purely organic order. The etiology of the Korsakoff syndrome is not simple, however. It may occur with other than alcoholic intoxications, although infrequently. Moreover, just plain hard drinking does not seem to produce it, for one finds that the patient has, as a rule, been eating no food for some weeks and has been subsisting on alcohol alone or nearly so. Finally, it has a seasonal incidence. The peak of the curve in New York State comes in the early fall, about the month of September.

The third plainly organic condition is that of gradual slowing of the mental processes, with memory and consequent judgement defect. That is usually due to an arterio-sclerotic affection of the brain, and, of course, when one is dealing with arterio-sclerosis one is always faced with a complicated problem in etiology. Alcohol in these cases is always only one, and often only a contributory, factor.

From these examples we learn that alcohol may affect the brain, either acutely or chronically, to disturb and retard the

intellectual or mechanical functions of the mind. This destruction may proceed to such lengths as grave dementia.

When we turn to the other alcoholic psychoses, to the ones which cause most social complications, a rather marked contrast is apparent. The simplest of these is known as the acute alcoholic hallucinosis. At the close of a spree the patient suddenly begins to hallucinate attacks being made upon him and to hear voices accusing him of homosexual practices. This mental content is extraordinarily stereotyped. As a rule the psychosis lasts only for a few days and may even clear up before the patient can be certified. In contrast to the psychoses we have been considering these cases show no clouding of consciousness, defect of memory, or any such symptoms. They seem merely to have been suddenly possessed with queer ideas of extraordinary vividness, and after recovery they seem just as normal as before. A few drinks in many normal persons will produce as much disorientation as is shown by these patients. On the other hand these attacks are apt to recur, and in later ones they may not lead to recovery but glide over into dementia praecox. Moreover, dementia praecox patients may show episodes with practically identical symptoms, although the subjects are abstainers; or the alcoholic hallucinosis may appear after drinking a relatively small amount of alcohol. Such facts have led some psychiatrists to think that this psychosis is virtually a psychogenic reaction liberated by alcohol; that it is, so to speak, an acute dementia praecox reaction, essentially constitutional, that appears when alcohol removes the normally acting inhibitions.

Probably the most troublesome of all alcoholic patients are those in the paranoid group. Such individuals may be normally sociable and good-tempered but after a drink or two imagine slights or insults and become dangerously quarrelsome. Many details lead one to suppose that here again we are dealing with constitutional anomalies. Even when free from alcohol or before drinking has begun the subjects are apt to show peculiarities. They are frequently women-haters and affect the society of men exclusively. (Many overt homosexuals are recruited from their ranks.) They have difficulty in adapting themselves to any kind of discipline and rebel at authority. The foreman or manager is apt to be regarded as a prejudiced tyrant. They are not well adapted people—that is to say, their adjustments to social life are not easy and automatic. The corollary to this is, of course, that antisocial tendencies are latently strong in them. Drink brings the latter to the surface. Marriage makes the most persistent demand for social adaptation that we know of. This is the reason why so many of these men begin to drink only after marriage. The innate rebellion at this bondage appears when alcohol has liberated their inhibitions. They first become querulous and beat or abuse their wives every Saturday night. Later, when drunk, delusions of unfaithfulness appear which may become fixed. It may only be when this last stage is reached that cognizance is taken of what was mental disease from the first. The fate of these creatures is often pitiable. They are certified and interned. Once in the asylum, which for them is a house of refuge, they are free from the demands that have been too much for them to meet, and consequently their mental symptoms clear up. So they are liberated. But after a few weeks or months in the old environment the temptation to drink becomes more than they can withstand. Soon the whole story is repeated, but the dénouement is reached more quickly. After a few such disillusionments the authorities cease their efforts to maintain such patients in the outer world and they are incarcerated for life although showing few if any gross symptoms. Nothing but forced detention in well-organized industrial colonies can ever solve this problem.

The last type of alcoholic mental disease which we shall consider is difficult to describe, for its symptoms are indefinite. It consists in a gradual deterioration, a degradation of emotional rather than of intellectual process. In this it is to be distinguished from the arterio-sclerotic type, where memory and intellectual capacity generally are primarily affected. Here, however, with such faculties intact, or relatively so, the patients gradually become indifferent to their responsibilities, lose ambition, their affections wane. Often some paranoid ideas are present, or they may merely become bad-tempered. They are pathological loafers, good-for-nothings. Most of these cases do not find their way into

institutions. They are not mad enough to be regarded as dangerous, so they merely ruin the home in an undramatic way. This deterioration is a good deal like that seen in some cases of dementia praecox. Etiologically it is a question impossible to decide which is more important—the constitutional factor, or the physical effects of protracted poisoning with alcohol. If the latter operated alone we would expect to get a dementia of the arterio-sclerotic or senile type.

Even from this outline of the alcoholic psychoses it can be gathered that the etiology of these conditions is relatively pure only in the cases of delirium tremens and the Korsakoff syndrome. If, under this heading, one were to include these conditions alone the psychiatric significance of alcohol would be scientific rather than social, for these two psychoses are not of any great consequence statistically. The ravages laid at the door of alcohol are those attributable to other factors as well. In general terms one can formulate the rôle of this poison by saying that it liberates abnormal reactions that have been latent and at the same time increases whatever fundamental tendency to abnormality there may be. There is, then, a vicious circle.

To see exactly how this comes about a little analysis is necessary. We have seen that there are two general effects which alcohol produces. It dulls the intellect, either acutely or permanently; it stupefies. Secondly, by removing inhibitions, it liberates antisocial tendencies that have previously been unconscious. These antisocial tendencies are inextricably mingled as both cause and effect with general maladaptation. To prove this would require a long dissertation, but the nature of the argument may be indicated. Our individualistic strivings are repressed to the unconscious. If we are adaptable we can give some outlet to them in a socialized form as permissible personal ambitions. If we fail in adaptation these unconscious complexes tend to appear in a less permissible form. In other words, if we are happy and successful our unconscious minds are placated with indirect outlet and do not cause trouble, but if we are unsuccessful and unhappy we at once are apt to become antisocial. This disturbs adaptation, thus producing more failure and mental discomfort. Maladaptation and autonomous unconscious individualism therefore react mutually on one another as cause and effect.

We can now discern the psychological rôle which alcohol plays. Adaptation means contact with reality. When this is difficult to maintain one instinctively yearns to abolish reality or blot it from sight. Any drug which stupefies will do this. Hence the man who wants to forget the world drinks. He gains the desired release. If this were all, alcohol might be an unmixed blessing as an emergency measure. But unfortunately this release is purchased by impairing those very faculties that are needed to attain success, and, to make matters worse, antisocial tendencies are liberated at the same time, and these increase the maladaptation. The alcoholic drinks to forget and thereby increases that which he would forget. This is the vicious circle.

Although not ordinarily put into such definite and technical terms, all sensible people realize this to be true. That is why we hear people say, "If he could only keep away from whisky for six months!" Even if only vaguely understood these facts should be sufficient to keep rational people from excessive drinking. But we know that this knowledge avails relatively little. Why does it not? The answer goes right to the root of the problem of alcoholism. With normal people reason triumphs over impulse, and they imbibe in moderation. The alcoholic is, before he ever touches a drop, an abnormal person. Sometimes—and here economic factors play an important rôle—the abnormality is environmental in origin. A man or woman with a human soul is forced to lead the life of a beast. In normal times the numbers who, through no fault of their own, are doomed to such a life are relatively small. The bestiality of their existence is more often of their own or their father's making. The chief problem is that of the man who is essentially psychopathic, whose unconscious gets out of leash and forces him, willy nilly, to produce a state of mental obfuscation in which he may indulge in thoughts or behaviour incompatible with his conscious standards. The normal man may experimentally get drunk once or twice, but as a rule is a temperate drinker. This is the crux of the therapeutic problem. If the etiology of alcoholism were simply alcohol, mere abstinence would cure the condition.

Attempts at social reform must inevitably follow the principle of trial and error. But if experiments are to be at all intelligent, we should have in advance some notion of the factors involved, even if their relative strengths be impossible to gauge without experiment. Further, if the trial prove an error one should have some idea of what has caused the failure. Our last topic is, then, to discuss whatever inferences may be drawn from the psychiatry of alcoholism that would bear on the problem of drinking in general.

The normal man is a psychiatric fiction. He does not exist. All of us, in varying degrees, have the same difficulties in meeting the world as the unfortunates who demonstrate their incapacity dramatically in psychoses. In a caricature we may see peculiarities we miss in a miniature. Then, turning to the latter, we can discern what we previously were blind to. This is the larger function of psychiatry. The psychopath commits a kind of mental suicide in order to evade responsibilities too great for him, and to translate himself to a world of fancy where reality does not mock his efforts. We "normals" drug ourselves with cheap fiction, theatres, and moving pictures; we go to sleep; we take vacations; we indulge in vicarious progress and adventure in watching games and prize fights. Above all, we forget ourselves in social intercourse. But when a man is tired or oppressed with care how can he forget his obsessing anxieties or his self-consciousness sufficiently to become sociable? He can take a drink, and he does. If he be normal, a small amount of alcohol will give the necessary relaxation. Conviviality is more important for the maintenance of our mental stability and effectiveness than we realize, as is witnessed, if we stop to think, by the fate of those who utterly lack that capacity. The invariably cheerful and friendly person is never morose, sensitive, overbearing, a hopeless crank, or violently prejudiced.

It is because alcohol contributes to sociability that it holds the strong position it does among so many peoples. Let us compare its status with that of the narcotic drugs. In real emergencies the latter are infinitely more useful. As a noted physician said, "Without opium, no doctor would have the heart to practise medicine." As to the harm they do, the narcotics rarely, if ever, induce actual dementia, and, pitiful though the state of the individual addict may be, the mental aberration or degradation and the economic losses these drugs produce are statistically negligible compared with the ravages of alcohol. Yet society has placed its taboo on them. Public sentiment not only approves but demands laws regulating the traffic in these medicines. The differing psychological effects of alcohol and narcotics explain this difference in social attitude. Only abnormal people use the latter drugs, and their effect is, as a rule, merely to wipe out reality, not to release impulses, a too stringent consciousness is on guard against. An opium den shows little trace of sodality. Innumerable people, on the other hand, are made happier, and therefore, healthier, by moderate indulgence in alcohol.

Prohibition enthusiasts are prone to claim that the abolition of alcohol as a beverage would cause no one any harm and prevent all the misery now laid at the door of inebriety. If alcohol did nothing for the drinker except harm him their claims would be justified. But their unsound reasoning does not prove that prohibition is undesirable. The question is, Would the gain be greater than the loss? No one, I fancy, is wise enough to answer this question; I certainly would not attempt to do so. I am here neither as a propagandist nor an antagonist, but as an agnostic trying to consider factors often neglected in discussion of the problem. As such I shall close with a few remarks as to the possible evil consequences of prohibition.

One must remember that we live in an imperfect world, imperfect largely because we have not yet gained the capacity to govern our own instincts. Alcohol is a crutch that man has discovered to help him with this disability. Some patients find they can walk and even run when their crutches are taken from them, but the majority need some artificial support. Let us first consider the fate of the psychopath who has been a potator and becomes abstemious. His brain becomes clearer, his mind works better, he saves money, and has a chance to gain that happiness in successful adaptation which will maintain him in equilibrium. In other words, he is brought back to that point in his career when he began to drink. If his inebriety was accidental or a response to some calamity the consequences of which are past, he is a saved

man, but if not there is a tendency towards instability that will express itself somehow: in crime, in a psychosis, in character deterioration, or in social agitation that is pursued merely for the excitement it brings. I am reminded of two cases in this connexion. One was of a ne'er-do-well whom I persuaded to abandon drink. To my surprise he did so; also to my surprise a florid paranoid dementia *præcox* appeared in six weeks' time. The other man was a dipsomaniac recognized by critical associates to have brilliance to the point of true genius. Psychological treatment resulted in a disappearance of his periodic attacks, but he began to deteriorate morally. In a few months he had sunk to the level of a tramp. His history showed that antisocial tendencies had existed from boyhood on. To what extent had his dipsomania been a more or less harmless substitute for what was his ultimate fate? These, of course, are unusual and striking cases, but they remind one of the parable of the house that was swept and garnished; seven devils entered therein and the last state of that house was worse than the first. But parables are all—like my arguments—purposely one-sided. If effective prohibition were enforced "alcoholic" insanity would, of course, no longer appear. But one would have to watch statistics of crime and the constitutional psychoses before he could estimate how much drain on the public purse had been avoided.

For one inebriate there are at least a hundred people who drink in moderation. What would their fate be in an alcohol-free State? The changes would not be obvious, but they might be serious. True congeniality being under the new régime essential for lively social intercourse, society would be split up into smaller groups, and many individuals would become quite seclusive. Sectionalism is not healthy for society any more than solitude is for an individual. Then, too, a certain proportion of moderate drinkers crave and need excitement. As we are now dealing with a type that is moderately well adapted, we may presume that such people would not turn to flagrantly antisocial activities. But there would be grave danger of their indulging in that kind of political activity where the mere excitement of strife is an end in itself. As for the truly well-adapted folk, those who approach real normality, we can rest assured that abstinence would produce no untoward results at all. If one could estimate their numbers, one could answer, more or less offhand, the great question, Would prohibition be worth while?

Finally we must consider the problem of heredity. The experience of any physician shows that the alcoholic is not fecund nor do his progeny thrive. We do not need experiment nor statistics except to prove with exactness what we already know. But, if we are to look on this matter dispassionately, can we avoid the question, Is this good or bad? There can be no doubt that it is bad for society in any generation. The production of defective, badly nurtured and reared offspring inevitably throws a burden on society. But there is the race to consider. Eugenics exists in name only. If the true alcoholic be a psychopath is it well to let him reproduce? Assuredly not. What we ought to do is actively to prevent it, which sentimentality forbids. Alcohol eliminates the unfit. If we fail to treat the race with intelligent care should we prevent Nature from working her way, albeit it is blind, slow, and unkind?

DISCUSSION.

Dr. W. C. SULLIVAN (Superintendent Medical Officer, Broadmoor Asylum) said that the papers which had been read showed the sense of proportion and level judgement which were so necessary in dealing with this question. Most of the difficulties and differences of opinion were really due to exaggerations or partial truth, or the making of generalizations from isolated observations. With regard to alcohol in relation to mental disorder, on the one hand it had been asserted that alcoholic excess was almost always the consequence of mental disorder, and, on the other hand, that mental disorder was the consequence of alcoholic excess. Surely, if a sense of proportion were maintained, it would be realized that the cases of psychopathic inebriety were a mere drop in the alcoholic ocean; they were negligible by the side of those cases in which alcoholic excess was due to environmental and above all to industrial conditions. It was almost certainly unsound to suggest that alcoholic excess was an important cause of certifiable insanity—as unsound as it would be to suggest that general paralysis was the cause of kleptomania on the ground that most general paralytics were

addicted to thieving. It had also to be remembered that if a comparison was made of the regional incidence of alcoholism and of mental diseases as measured by admissions to asylums there was no such correspondence as one would expect to find. Finally, there was the evidence of the war years, which offered, he thought, quite convincing proof that for the most part alcoholism was a negligible factor in the causation of insanity. The speaker showed a table giving figures relating to alcoholism, attempted suicide, and insanity, amongst women only, in England and Wales, from 1913 to 1918 (the figures for men were not available).

	Convictions for Drunkenness.	Deaths from Alcoholism.	Deaths from Cirrhosis of Liver.	Attempted Suicide.	First Admissions to Mental Hospitals.
1913	35,675	719	1,655	983	9,372
1914	37,311	680	1,773	1,049	9,702
1915	33,211	584	1,525	816	9,078
1916	21,245	333	1,163	436	8,850
1917	12,397	222	803	452	8,702
1918	7,222	74	579	403	9,725

Under the system of physiological liquor control enforced by Lord D'Abernon there was considerable reduction in alcoholism in this country—in some cases a reduction of 70 per cent. But the admissions (of women) to asylums during the same period showed no decrease at all, but a slight increase. These figures were consistent only with the conclusion to be drawn from the pathological evidence of Sir Frederick Mott, that alcohol was a negligible factor in certifiable insanity. There were certain specific alcoholic forms of disease, but these, numerically quite small, exhausted the rôle of alcohol as a cause of insanity. To state it in a way that perhaps might appear absurd, the only insanity due to alcoholism was alcoholic insanity. But there were mental disorders, not reaching the level of certifiability, which were of great importance because they were a source of conduct disorders. Attempts at suicide represented a very common condition, and there was a large and, he thought, a convincing amount of clinical and statistical evidence to show that the attempt to commit suicide was ordinarily due to alcohol. That was very much what would be expected. There was no other agency of the same widespread character which so favoured the suicidal impulse and at the same time prevented its execution. It reminded him of a preacher on the west coast of Ireland who said to his congregation, "What makes you shoot at your landlords? The drink! And what makes you miss them? The drink!" In the case of crimes of violence and lust the conditions were more complex, and the same statistical movement could not be traced; but evidence was clear that murderous attacks on women by their husbands and the violation of children were more often due to alcohol than to any other cause. Alcohol, at least before the war, was an important cause of mental disorders, not amounting to certifiability, but leading to serious crime. Nowadays, under the partial operation of the policy which was introduced during the war, the alcohol problem was not nearly so important as previously.

In reply to the Rev. AMY RENWICK (Penzance), who asked whether the war had not introduced causes which explained the increase in cases of insanity among women, Dr. SULLIVAN said that his statistics were merely returns of first admissions, but he believed it to be the general view that the war did not affect the female population in any direction likely to produce a considerable increase of insanity.

Captain ARTHUR ST. JOHN (Stirling) described the procedure adopted in the State mental hospital in Massachusetts in dealing with alcoholics. The régime was arranged, in the first place, to bring about the physical improvement of the patient; secondly, to cancel out if possible the particular cause of his inebriety; thirdly, to sustain his interest in the world of affairs, and return him to congenial occupation and environment; and, finally, to give him an extended educational treatment in the out-patient department, the work of which department was a great feature of the system. The percentage of improved cases under these conditions was 64. The people thus received were 80 per cent. voluntary cases, and the remainder were custodial cases, committed to the hospital by the magistrates on the certificates of two medical men.

(To be continued.)

THE SECTIONS.

BRIEF SUMMARY OF PROCEEDINGS.

ARRANGEMENTS have been made to publish full reports of the discussions in the Sections of the Annual Meeting at Glasgow during the next few months. Meanwhile, the brief notes of the first day's sessions which follow will enable those who were not present to gain a general view of the proceedings. Any errors to which attention may be drawn will be corrected in the full reports.

SECTION OF MEDICINE.

Wednesday, July 26th.

AFTER a few introductory remarks by the President, Professor T. K. Munro, Professor Hugh Maclean (London) opened the discussion on the prognosis and treatment of chronic renal disease. He began by pointing out that in recent years our conceptions of renal disease with regard to prognosis and treatment had become greatly altered; this was chiefly due to the information which was now obtainable as to the efficiency of the kidneys by the renal efficiency tests now employed. In dealing with chronic renal disease Professor Maclean explained that he recognized two main types—namely: (1) Hydræmic nephritis, in which there was very marked oedema, retention of chlorides and water, but no retention of nitrogen and no increase of urea. He pointed out that this type was really not a chronic form so much as a subacute form. (2) Chronic interstitial nephritis, in which there was very little retention of water or salt and no oedema, but there was a tendency for retention of nitrogenous products and a great tendency for cardio-vascular changes to occur. Professor Maclean said, however, that it was not unusual to get a mixture of the two types. Prognosis, Professor Maclean went on to say, should be based upon three main factors: (1) the general clinical condition of the patient, (2) the state of the cardio-vascular system, (3) the biochemical tests. In discussing these factors Professor Maclean emphasized that in his opinion the tests for renal efficiency were of greater value than the clinical symptoms, and instanced many cases in which symptoms had been entirely absent but the efficiency tests had given the clue to the condition present. As a general rule he relied most upon the estimation of the blood urea and the urea concentration tests as the most valuable and the most practicable. He reminded his hearers that one single blood urea test was seldom of value, as it might indicate only a temporary state. He also employed the diastase test, but regarded its value only as confirmatory. He did not consider that as a test by itself it was reliable. The state of the cardio-vascular system, Professor Maclean said, must not be overlooked, but he pointed out there were many instances in which the cardio-vascular system might be partly affected without much damage having been done to the kidneys. As regards treatment, Professor Maclean discussed mainly our new conceptions as to diet in chronic renal disease. He pointed out that in the hydræmic variety if there was no retention of nitrogenous products the indication was to give proteins in full amount and not withhold them as was formerly practised. In the severe cases, however, it was best to stick to the low protein diet. Decapsulation of the kidney promised good results for the future.

Dr. Comrie (Edinburgh), who followed in the discussion, agreed with Professor Maclean as to the value of the biochemical tests. He placed great reliance on the phenol-sulphonaphthalein test, and held that a result of 50 per cent. indicated a good prognosis, and 30 per cent. and under must be regarded as indicating a bad prognosis. Dr. Symes (Bristol) confined his remarks to chronic parenchymatous nephritis, and pointed out that it was a bad name and one which he hoped to see disappear very soon. It was only a stage of diffuse nephritis, and not necessarily of so grave prognosis as the textbooks made out. He agreed with what Professor Maclean had said about the treatment of the condition, and urged also the value of iron and arsenic as drugs. Professor Shaw Dunn (Birmingham) dealt with the histology of the kidneys in chronic nephritis, and described the changes that occur as falling into two main classes—namely, atrophic changes and destructive changes. He admitted, however, that most cases were a mixture of the two types. Dr. Katherine Robertson gave a description of six fatal cases which had been carefully considered clinically and at

necropsy. Dr. de Wesselow (London) pointed out that high blood pressure was not necessarily due to retention of toxic products, and instanced the polycystic kidney, in which there was no raised blood pressure in spite of high urea retention. He regarded the phosphates in the blood plasma and the calcium content in the serum as possibly important factors. Dr. Tidy (London) thought it was our duty to try to correlate more the clinical symptoms of the disease with the histology of the kidneys. He did not agree with former speakers that the histological types could be clearly divided into two classes. There were, he held, at least four types. He deplored that recognition had not been given during the discussion to the small white kidney. It was a definite clinical type with definite pathological changes. Dr. Toyo (Birmingham) spoke of the value of the biochemical tests in general practice. Professor Monro (Glasgow) reminded the Section that the old-established methods of investigation must not be given up because of the undoubted value of the new tests. Professor Maclean, in replying, made clear some of the points of controversy which had arisen during the discussion. Over 150 members attended the opening session.

SECTION OF MICROBIOLOGY (INCLUDING BACTERIOLOGY).

Wednesday, July 26th.

Dr. ROBERT BUCHANAN, in opening this Section on July 26th, reviewed the development of bacteriological science and indicated the wide field to be covered by the programme.

Dr. F. d'Herelle, of the Pasteur Institute, opened the discussion on the bacteriophage. After stating the well-established fact that filtrates from organic material are capable of inducing lysis in bacterial cultures, he dealt with the possible explanations for this phenomenon and brought forward certain facts as proof of his contention that bacterial lysis is caused by the activity of a living ultra-microscopic parasite of bacteria, named by him the bacteriophage. He pointed out that the dissolution of bacteria under the influence of the bacteriophagic principle takes place in series and can be carried over from tube to tube; that the filtrable corpuscles multiply in the course of the bacteriolysis; that all bacteriophagic ultra-microscopic corpuscles, grown at the expense of any bacterial species, constitute one and the same antigen; that the ultra-microscopic corpuscles possess a variable virulence that by successive passages it is possible to raise the virulence of a feeble strain; that the bacteria defend themselves and are even capable of acquiring immunity towards the parasite; and that the bacteriophage is capable of adaptation. He declared his opinion that the phenomena described by him as due to a parasite were different from the lytic phenomena described by Twort in 1915.

Dr. F. W. Twort began by stating that the bacteriolysis described by d'Herelle could not be differentiated from the processes described by himself in 1915, and attributed at that time to an acute infectious disease of micrococci. He reviewed his earlier work on ultra-microscopic viruses, and pointed out in particular that lysis had been observed in sealed cultures of micrococci kept for a long time and apparently pure. In such cases the lytic agent seemed undoubtedly to have been produced by the bacteria themselves, for they had not come in contact with any external agent. Whereas, he declared, the possibility of the lytic agent being an ultra-microscopic virus had not yet been disproved, it seemed possible, but by no means certain, that the active transparent material found in cultures was produced by the micrococci. He brought forward evidence derived from his recent researches to show that in a bacterial colony special forms might develop possessed of special functions, and that more stable and resistant types might be separated from an apparently homogeneous culture. Such special forms of bacilli might be dissolved up for the benefit of the bacterial community, and the lytic agent might be formed for the purpose of carrying out this lytic action and setting free toxins contained in the special forms. Dr. André Gratiat of Brussels was of the opinion that the Twort and d'Herelle phenomena were identical. He found no evidence of the existence of a living organism, but attributed the phenomenon to a chemical substance excreted by the bacteria themselves, his reason being the parallelism between the activity of bacterial growth and the production of the lytic agent, the similarity to chemical affinity as shown by the absorption of the lytic agent by dead bacilli, and the fact that lytic agents are antigenically specific. Dr. Ledingham expressed

himself as unconvinced of the existence of any ultra-microscopic bacterial parasite, and appealed for a more exact study of the simpler processes of bacteriolysis. Dr. McLeod described experiments on the inhibition of bacterial growth by the products of bacterial metabolism. Dr. Fleming demonstrated the existence of rapid bacteriolysis caused by egg albumen and animal secretions, such as tears. Dr. A. W. M. Ellis reported on some quantitative experiments which lead to conclusions contrary to d'Herelle's hypothesis. Professor D. Ellis described a form of bacteriolysis of sulphur bacteria due to degeneration. In his reply Dr. Twort expressed himself as still convinced of the identity of the so-called Twort and d'Herelle phenomena, whereas Dr. d'Herelle brought forward fresh evidence of their dissimilarity, derived chiefly from the experiments recorded by Dr. Fleming.

A short summary was read of a paper by Dr. Wiseman on an outbreak of food poisoning by milk, caused by *B. aertrycke*, the first example of such a form of food poisoning yet reported. The source of the epidemic was not determined, but the author laid great stress on the fact that the stools of the patients affected were very watery and contained much mucus, a fact which served to favour a diagnosis of dysentery rather than the paratyphoid group infection. Dr. R. G. Robertson read a summary of a paper on "The toxins of *B. dysenteriae* Shiga," describing experiments in the detoxication of cultures of Shiga's bacillus. By means of a special technique he succeeded in preparing a non-irritating vaccine possessed of marked protective qualities. Sir William B. Leishman spoke highly of this research, and congratulated Dr. Robertson on his results.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Wednesday, July 26th.

THE President, Professor G. M. Robertson, in opening the proceedings on July 26th, deplored the separation of neurology and psychology, which was disastrous for both, and welcomed the combination of the Sections at the present meeting. Psychotherapy came to the fore during the war, the public taking a great interest in it, and the medical profession should express itself clearly on the subject. Psychotherapy was the oldest form of treatment—the methods of cure in the Bible were psychotherapy pure and simple; the successful medical man was the successful psychotherapist, though he might not know it. Dr. T. W. Mitchell (Hawley) read a paper on "Psychotherapeutics and psychopathology," in which he traced the development and growth of psychotherapeutics from the ancients and claimed that psychotherapy not based on the method of Freud could be little more than empiricism, and only be fully developed when psychopathology was accepted as a necessary part of general pathology. The close relationship between mind and body was recognized in everyday life. The extent to which psychotherapy was of value in the treatment of organic and functional disease was only realized by those engaged in it. Many practitioners of psychotherapeutics had little knowledge of it before the war; in the war practically all cases were examples of neurosis, and as they have had very little opportunity of treating other types since the war their views are biased by war experience. In hypnotism and suggestion persuasion was largely adopted, and the appeal to reason; but for success explanation need not be true, though the patient must believe that it was. Clues to the origin and nature of illness were not within the patient's power of conscious recollection. In the treatment of war neurosis suggestion was often most unsatisfactory, and other means were required to restore health. Reassociation of dissociated memories, hypnosis to discover them, and suggestion as a means of restoring them were widely used. Suggestion in war cases by itself had no rational basis; mental conflict and repression together had accounted for many war neuroses. Psycho-analysis as a pathological and a therapeutic measure was considered, and the different standpoints of pathologist and therapist detailed.

Dr. J. A. Hadfield (London), in discussing "The making of a neurotic," said three phases were required: (1) the formation of complexes, (2) conflict of complexes, (3) the emergence of symptoms. Hereditary influences were at first considered of the greatest importance, but psycho-analysis and hypnotism had shown the influences to be in the main environmental; many conditions were handed down from parent to child by suggestion and imitation, not congenital in

reality, but due to influences of early environment. Environmental disturbances could be cured, and an hereditary cause should not be diagnosed until environment had been excluded; mental deficiency should, of course, be excluded. Psychoneurosis could not be inherited, but the soil might be transmitted; the nervous temperament was inherited, but was in itself not pathological. Instincts were psychophysical and inherited. Sentiments were those consonations which were acceptable to us—home, country, religion, etc. Organized together into "accepted self," will was the function of organized self. Complexes were consonations which were displeasing to us; they tended to become split off and were the cause and origin of psychoneurosis—fear, inferiority, and sex complexes. Most important were those which concerned self. Origin of all psychoneurosis was egotism—using the term in the widest sense—in some form. Psychoneurosis might date back to the third year of life, when self-consciousness was first developed; fantasies were then formed and became repressed, their occurrence was forgotten and only revealed by analysis. Failure to live up to a fantasy might cause a breakdown. Symptoms were not due to a single complex but to a conflict between two complexes. Biologist and psychologist looked at life from different aspects; a man broke down because he could not adapt himself to himself; a soldier broke down under shell fire because of the conflict between duty and fear. The conflict was endopsychic. Removal from environment was not sufficient to cure—recognition of the patient's change of attitude towards himself was essential, and in analysis both complexes must be traced.

Dr. Jano Suttie (Glasgow) read a paper on "The mental stresses of adjustment in women," which was highly appreciated. She said that certain stresses peculiar to women were commonly found in the neurotic: (1) The different maternal attitude to son and daughter. In present-day families girls were not valued as highly as boys, to the relative disparagement of girls. Childish jealousies produced the inferiority complex. Daughters were more influenced by the maternal preference. (2) Domestic skill had to be acquired by girls, but was not necessary for boys; the girlish virtues were repression, not expression, of self. (3) The contemplation of life from two sides—marriage or occupation—led directly to conflict. (4) The menopause exerted a variable influence depending on the previous mode of life. (5) Economic stress against biological instincts. Dr. H. Crichton Miller (London), in discussing the "Psychic and endocrine factors in functional disorders," began by saying that he used the phrase "functional disorder" in a purposely loose sense to avoid excluding a somatic etiological factor. All should aim at binocular vision, but the difficulties on both sides were serious; the psychic notoriously eluded scientific treatment. To an almost equal extent the endocrine factor baffled us. We could not ignore the evidence of universal human experience—the association of physical characteristics and mental traits. We should study in each case—(1) inherited endocrine pattern, (2) personal endocrine history, (3) personal emotional history. He suggested that the thyroid supplied the creative factor, the pituitary the imaginative "power urge," the adrenals the objective "power urge." From this could be framed a hypothesis of the various constituents of the human dynamic. Dr. C. F. Harford (London) regretted that there was no standard of medical psychology to go on; psychology was almost unformed. He referred to Dr. Rivers's lecture in Manchester on psychical determination. Students should believe in the law of causation; nothing is due to chance or accident, but the idea of psychical determinism does not interfere with some belief in free will. There were many points of controversy, but all should look for agreement. Three factors were common to all symptoms: (1) belief in the unconscious; (2) unconscious can only be reached through certain methods; (3) whatever the technique in the ultimate event, it must be acceptance of the individual, and the ultimate process is one of auto-suggestion. He appealed for study of the methods of Coué, and in association with Dr. Monier Williams he was at present testing his work and methods. Dr. Gordon (Bath) said there had not been much advance in psychotherapeutics during the last two years. Psychology and biology were not antagonistic, and all psychoneurosis was not due to sexual influences. The unit of any process corresponded to a reflex arc set in motion by a stimulus which might be a mental or biochemical change, and it was on these lines that psychopathology should be built up. Psychotherapists must work on a wide basis of physiology as a whole if progress was to be made. Dr. Murray Lyon

(Edinburgh) said that hypnotism had been largely abandoned and suggestion was the main means of all treatment in one form or another; there was nothing new in what Coué said. Syphilitic neurotics were all potential tabetics or general paralytics, but by suitable treatment the development of these diseases should be prevented. Insomnia, lightning pains, and ataxia of tabes had been controlled by suggestion. Dr. Council (Edinburgh) agreed with Dr. Hadfield that every symptom was due to endopsychic conflict—sexual instinct was almost invariably involved as one factor. The environmental factor was of great importance. Dr. Calwell (Belfast) said that consciousness was of gradual evolution, and prenatal influences and forces acting in the first two or three years of life must not be neglected in discussing a causation of psychoses. Psychology was physiology of the higher centres. The influence of inheritance was very strong in disposition, tendency to thought, and mannerism. The influence of the state of the skin and muscles might be of importance as well as the condition of the endocrine glands. Dr. Helen Boyle (Brighton) thought Dr. Suttie had been unduly pessimistic about the outlook for women. Temperament played a very important part—"Give the child a start with no feeling of inferiority to her brothers, praise her for what she is good at, and she will do whatever she has to attempt well." Girls must know their limitation, whether submissive or aggressive; there was plenty of room in the world for all sorts. Dr. Smith (Peterhead) asked if there was any agreement in the profession as to whether the conscious or unconscious brain was the predominant part. The President said he was not disposed to answer Dr. Smith's question, and moved the following motion, which was carried unanimously:

The members of the Section of Neurology and Psychological Medicine of the British Medical Association are of opinion that instruction in psychology and psychopathology (medical psychology) should form part of the curriculum of all medical students, and further, that this opinion should be brought to the notice of the General Medical Council and all the teaching bodies in the United Kingdom and Ireland.

He added that a course of lectures in psychology had been started in Edinburgh, and was being well attended.

Dr. Hadfield briefly replied to questions which had been raised on his paper.

SECTION OF GYNAECOLOGY AND OBSTETRICS.

Wednesday, July 26th.

THE subject for discussion on July 26th was "Stillbirths and neo-natal deaths." In his introductory remarks the President (Professor Ewon J. Maclean of Cardiff) pointed out that the national importance of the subject only needed to be mentioned to be accorded. As fertility was the index of the present and the earnest of the future prosperity and strength of a nation, he thought that even the contraceptionists would approve of their objective, though it was anomalous from the national point of view that their propaganda should be allowed to proceed unhampered. He thought that so far as the population of the country was concerned the requirement might arise in the not distant future for the law to develop an ante-conceptual in addition to a post-conceptual application. In calling upon Dr. J. W. Ballantyne (Edinburgh) to open the discussion the President referred to him as "truly a pioneer of international status in ante-natal investigation." Dr. Ballantyne then read a paper on "Ante-natal, intra-natal, and neo-natal death: causes, pathology, and prevention, with special reference to ante-natal death." In opening, he remarked on the coincidence that in 1888, on the occasion of the last meeting of the Association in Glasgow, the discussion in this Section was also on ante-natal death, and he touched upon the limitations of the subject as they then existed. Dr. Ballantyne then proceeded to deal fully with the classification of the causes and the prevention of foetal death. He exhibited a most instructive table to illustrate how great a reduction in the stillbirth rate in Edinburgh had been brought about since ante-natal supervision and treatment had been practised. In conclusion, he urged strongly that every mother should be placed in the position to receive proper ante-natal care. Dr. Eardley Holland (London), in following, dealt more particularly with intra-natal death. He emphasized that examination of a large number of stillborn foetuses proved that a larger number died from the complications of labour than from foetal or maternal disease. *Post mortem*, these foetuses showed evidence of cerebral or visceral haemorrhages. It was remarkable how frequently the tentorium cerebelli was torn. He had found that in 83 per cent. of deaths of the child in

normal breech deliveries this condition was found. He urged that delivery of the after-coming head should not be unduly hastened. In conclusion he showed a series of lantern slides to demonstrate the lines of stress in the falx cerebri and the tentorium cerebelli to illustrate where tears were most likely to occur as the result of the moulding of the head. Professor Louise McIlroy (London) dealt with the subject from the point of view of the toxæmias of pregnancy. She confessed that her work so far had only made her feel more ignorant of the subject than when she commenced. She felt that the causes must be sought, not in the post-mortem room, but in the metabolism of the mother. Her view was that the chief causes of toxæmia came from the intestine—for instance, septic teeth, constipation, and so on. She enumerated the various lines of investigation she was following at present. She urged strongly that a commission of inquiry should be set up to go into the whole question thoroughly and to lay down the lines of investigation and give rules to be followed in ante-natal work. Professor A. M. Kennedy (Cardiff) was unfortunately unable to take part in the discussion owing to an attack of influenza. Further papers were contributed by Dr. F. J. Browne (Edinburgh), who also showed a very illuminating series of lantern slides showing the microscopic changes found in the various foetal organs and the placenta as the result of syphilis; by Dr. J. N. Cruickshank (Glasgow), who discussed "Syphilis as a cause of ante-natal death"; and by Dr. Gilbert Strachan (Cardiff) on "Placental changes in relation to foetal death." A discussion then ensued, in which Dr. T. W. Edon (London), Dr. Laphorn Smith (London), Dr. Russell Andrews (London), Dr. Anderson (Glasgow), Professor Munro Kerr (Glasgow), Professor R. J. Jolmes (Belfast), Dr. Stewart (Glasgow), and the President took part. Dr. Ballantyne then briefly replied.

In the afternoon there was a demonstration in the Pathological Museum of specimens illustrating ante-natal and neo-natal pathology by Drs. J. N. Cruickshank and Hewitt (Glasgow) and syphilis in the newborn by Dr. F. J. Browne (Edinburgh).

SECTION OF PATHOLOGY.

Wednesday, July 26th.

THE President (Professor Robert Muir, F.R.S.) having welcomed the Section to Glasgow, Dr. J. A. Murray (Director, Imperial Cancer Research Fund, London) expressed the regret which all felt at the absence of Professor Fibiger of Copenhagen, who was prevented from coming to open the discussion in person. It was to Fibiger with his epoch-making experiments in the *spiroptera* cancer in rats that we owed the great advance that had since taken place in the particular aspect of research they were to consider that morning. During the war Japanese observers had claimed to have produced malignant tumours in rabbits by the long-continued application of coal tar; their evidence was not homogeneous, and it was fortunate that another Japanese worker, Tsutsin, repeated their experiments on mice and produced indubitably malignant tumours. The mouse was peculiarly suitable for such studies in that the duration of its life was about one-twentieth of that of the human subject, and one could elicit the whole story of malignant disease in that animal in a short period of time. Other laboratory animals were less satisfactory and more resistant to the process. Dr. Murray then discussed a single series of experiments with tar on mice. Using whole tar, alcoholic extract, and ether extract of tar, he found he got many more tumours with the last; and having applied simultaneously the three to different parts of the same animals he found that malignant tumours might result from any one of these, but not from the whole in any one animal, and he concluded that cancer, having once started in a single situation, conferred an "immunity" in the animal against the development of further primary malignant tumours elsewhere.

Dr. Archibald Leitch (Director of the Cancer Hospital Research Institute, London) then communicated for the first time to the Section the recent results he had obtained while endeavouring to establish on a broader basis the causal connexion of certain irritants with cancer. He pointed out that in certain industries, and in very striking instances, a specific substance had been implicated, and that the dispute seemed interminable between those who regarded such agents as a predisposing cause and those who maintained that such irritants were the proximate cause of the neoplastic response. He had endeavoured to apply the experimental method in

these cases, and, while not claiming that the reply absolutely established a direct relationship, he maintained that it supplied considerable support to the theory of the irritant being the *primo* cause of tumour production. Apart from his tar experiments which had previously been communicated, he added two more successful cancer producers. Starting from the knowledge that cancer had been known for the last fifty years to occur in Scottish paraffin workers, he had applied for many months various distillation products of shale oil to the skin of large numbers of animals. The results, in mice in particular, were most interesting. In many of these animals, after a period of four months, wart formation took place, generally multiple, and these slowly gave place to true infiltrating malignant epitheliomata. In some instances, indeed, two or three independent epitheliomata developed in the same animal, and on one occasion he produced a spindle-celled sarcoma. Only one mouse in his whole series remained quite refractory to tumour production. Dr. Leitch then demonstrated an even more interesting series of experiments. Starting from the opinion of Jonathan Hutchinson that the long continued use of medicinal arsenical preparations could induce skin cancer, he related the success which he and his colleague, Dr. E. L. Kennaway, had obtained by painting mice with a solution of arsenic one hundred times weaker than Foyler's solution. They had produced in addition to papilloma a rapidly growing epithelioma with metastases in the lungs. To the already known agents, that produced cancer experimentally in animals—the *Spiroptera neoplastica* of Fibiger, the tar of Yamagiwa, and the *Cysticercus fasciolaris* of Curtis and Bullock—he thus had the honour of adding two more—namely, paraffin and arsenic. He had used and was still using many other suspected agents, and he believed that they would discover a large number of substances, in no way related chemically, which were capable of directly inducing neoplastic reactions. Dr. Alexander Scott (Bromburn) gave the results of twenty-two years' experience among the Scottish paraffin workers, a paper which was excellently illustrated with pictures of paraffin dermatoses and tumours. He had seen and carefully studied from the beginning the development of epitheliomata on the exposed parts of the workmen in 19 cases, and had traced the occurrence of 44 cases altogether amongst the employees. Roughly speaking, 5,000 workmen formed the population in which such cases occurred; and of these cutaneous cancers 63 per cent. occurred on the arms, which were directly exposed, and 30 per cent. on the scrotum, from the oil-soaked trousers. Multiple growths were not uncommon, even on the scrotum, and in most cases these were not metastases or recurrences but independent developments. The pre-tumour stage of dermatitis erythematosa took from ten to fifteen years for its development; the workmen who developed epitheliomata had been working in the paraffin sheds for twenty to forty years. This interesting communication from a medical man in general practice was recognized as being the result of a study of the conditions which was unique. Owing to the measures adopted now the disease was in a fair way of being completely abolished.

Dr. T. M. Legge, of the Home Office, spoke of the incidence of cancer formation amongst workmen engaged in the pitch and tar industries. He said that such epitheliomatous ulcerations were not notifiable by law and that certain regulations had been drawn up for these trades. Owing to the representations that had been made, industries using blast-furnace tar were excluded. He had never seen nor heard of epithelioma occurring in association with blast-furnace tar; and, in reply to a question, Dr. Leitch had stated that though he could easily and frequently induce tumours with ordinary gas tar, he had not succeeded in obtaining a single positive result with blast-furnace tar. During the last eighteen months 95 cases of epitheliomatous ulceration had occurred amongst workmen in the pitch, tar, and paraffin industries. But it was interesting to note that in the chrome industries, where severe and very chronic ulcerations were not infrequent, no case of epithelioma had ever been found.

Mr. Cecil Rowntree (London) communicated a paper on x-ray cancer. He had traced all the cases that had been known to have occurred in England. In all these an x-ray burn had occurred at some time or other, and probably long-continued smaller doses were essential. It was curious that the disease was practically confined to the back of the hands, even the slender protection afforded by the sleeves being sufficient to exclude the kind of rays that produced epithelial changes. No case had occurred for a large number of years, and it was probable that owing to the precautions now universally

adopted no more cases would occur amongst x-ray workers. It did not follow that all who had an x-ray burn would develop epithelioma, as some radiographers who had met with such an accident as long back as eighteen years were still free of all suspicion of malignant changes. Dr. J. Cruickshank (Aberdeen) related some points that had impressed him in his experiments with tar. He had employed a sample of coal tar that was ten years old, and out of sixty-seven mice that formed the series in the experiment twenty developed malignant tumours. At least 50 per cent. of his tumours showed multiple sources of origin. Many were of a very chronic nature, and two showed lymphatic gland metastases. Both young and aged mice reacted similarly to the irritant. He was struck with the extreme degree of keratinization manifested, not only in the primary growth but in the metastases—a feature which was certainly uncommon in the skin cancers of man. He was of opinion that in most cases the tumours arose from the hair follicles, and not from the superficial epithelium, contrary to the opinions of Dr. Murray and Dr. Leitch, and in this way the multiple origin could be explained. Dr. Passcy (London) stated that he had sought to obtain from soot an active tumour-producing fraction, and had found such a fraction by mixing the soot with lime and then extracting with ether. Applying such a fraction to mice he produced tumours in 50 per cent. of the animals in six months, warts beginning to appear at the tenth week. He took two series of mice, one fed on a diet deficient in fat-soluble vitamin, and the other on a ration rich in this vitamin, and applied the ether fraction to both. There was nothing to choose between them in results, both giving about 45 per cent. of tumours.

In the informal discussion that followed these very important papers Dr. A. J. Campbell and Dr. Hollins held that three things were essential for cancer formation—an abundant blood supply, a degenerated epithelium, and an irritant, the last causing the cells to revert to the germinal type. Dr. McKail related two cases of pitch cancer; and Colonel Mackie, I.M.S., spoke of betel-nut cancer in India.

SECTION OF PUBLIC HEALTH.

Wednesday, July 26th.

THE Public Health Section opened on Wednesday, July 26th in the Natural Philosophy Department of the University, with a rather meagre attendance, but numbers rapidly increased. The President of the Section, Dr. A. K. Chalmers (M.O.H. Glasgow), occupied the chair, and delivered the opening address, entitled "A plea for the study of biology in relation to public health." As an introduction to the subject he reviewed the more striking advances that had taken place in public health administration since the British Medical Association last met in Glasgow thirty-four years ago, and this comparison led him to ask whether the horizon had lifted so as to disclose objectives then hidden, and whether the same spirit which inspired our predecessors remained still with us. He thought a comparison of the records of the former meeting and of this would supply a sufficient answer; but in addition there was the testimony of the falling death rate, the diminution in severity of the infectious diseases, and the gradual extinction of the "plague" diseases. Legislation had advanced, barriers of prejudice had been broken down, and one field after another had been brought within the scope of regulated effort; but though each had played its part in the control of disease they were not the only factors. "Do we not," he asked, "too often forget that Nature is silently at work, often doing better for us than we know?" And on this he based his plea for a fuller study of Nature's method of adapting life to its varying conditions. In conclusion he exemplified the "new horizon" by reference to recent work in connexion with infant mortality, tuberculosis, and venereal disease, at the same time returning an effective answer to the trite criticism of preserving the unfit so often levelled at preventive medicine.

The first paper in the Section was one by Dr. R. J. Reece of the Ministry of Health, which traced the development of port sanitary administration from the early days when the authorities of Venice first drew up a code of quarantine regulations down to the present day. He was careful to point out that merely restrictive measures were insufficient to prevent the ingress of sea-borne diseases, that much depended upon the probity of the officers of the mercantile marine, and that it was also a necessary part of the scheme to see that the general sanitation of the vessels was brought up to a reasonable standard. In the discussion which followed Dr. Dearden (M.O.H. Port of Manchester) complained that too little was

known by the general public of the value of this "first line of defence," and that the powers of the port medical officer were not yet sufficiently large to make his work so effective as it might be. Dr. King, who represented the Public Health Service of the United States, followed with an interesting comparison of their methods and ours, and referred to the difficulties which arose when there was a conflict between trade interests and health interests. Major Jackson, R.A.M.C. (ret.), gave his personal experience of the control of plague, cholera, yellow fever, small-pox, etc., in Indian ports, and the great difficulty of getting the natives to understand or observe the simplest rules of hygiene. Dr. J. C. McVail drew attention to the advantage of the American system, whereby immigrants came under expert observation at the place of embarkation; and Dr. Herbert Jones emphasized the usefulness of the slips sent by port medical officers to their inland colleagues intimating the destination of contacts from an infected ship.

The second paper was by Lieut.-Colonel Fremantle, M.P. (Consulting C.M.O. Herts), upon "The economics of public health," in which he endeavoured to show, in cash values, the loss occasioned by sickness, disablement, and death; and, *per contra*, what saving could be effected by the elimination of a disease such as tuberculosis. Upon conclusion of the paper Dr. Macfadyen gave a lively impetus to the discussion by declaring that the work in Glasgow, though admirable, had gone beyond the point which was economical. With this statement Dr. Herbert Jones absolutely disagreed. Too much was not being spent on the public health services. If the amounts were expressed in terms of rateable value it would be found that extraordinarily little was being spent as compared with, say, the upkeep of roads. Dr. Miller (C.M.O. Radnor) advocated as a measure of practical economy the reconstitution of sanitary districts and the avoidance of overlapping duties between county and district medical officers of health. The next paper was that of Dr. Brownlee (Director of Statistics, Medical Research Council), in which he discussed the interpretation of the death statistics of infancy and childhood in relation to development and environment, but, as Dr. J. C. McVail observed in thanking and congratulating the author, it was one to be read studiously and not discussed in summary fashion.

The final paper for the session dealt with puerperal mortality in Scotland, the author being Dr. T. F. Dewar, C.B., of the Scottish Board of Health. In a masterly fashion he showed that in this respect there had not been the improvement hoped for; in fact, recent figures did not compare at all favourably with those of former years. It was not his place, he said, to apportion blame, but merely to state the position as disclosed by the statistics he had compiled. A lively discussion followed, in which the "blame" was successively placed upon insanitary surroundings (Dr. Herbert Jones), the want of surgical technique (Dr. Shannon of the Glasgow Maternity Hospital), too much handling of the patient (Lieut.-Colonel Fremantle), too free use of instruments (Dr. Picken, M.O.H. Cardiff); but Dr. Morris (M.O.H. Neath) protested against blame being placed on the medical practitioner, though he admitted midwifery practice was in need of improvement, while Dr. Lewys Lloyd (C.M.O. Merioneth) also lodged a protest against the loose phrasing used in assigning blame to doctor or midwife. Nurse Barker (Inspector of Midwives, Glasgow) brought the discussion to a happy conclusion in laughter by describing how midwives often came to her *in tears* over the injuries done by doctors in trying to hustle nature.

SECTION OF SURGERY.

Wednesday, July 26th.

THE large surgery classroom was completely filled on the first day of the Section meetings. Professor Alexis Thomson presided, and was supported by the officers of the Section. In introducing the discussion on cholelithiasis Professor Rutherford Morison (Newcastle-on-Tyne) sketched the recent history of the surgery of gall-stone disease, with especial reference to his own part in it and to the evolution of the present-day opinions. In searching for the causation of the formation of gall stones, he now thought that infection of the gall bladder—the universally popular acception—was insufficiently supported by the evidence adduced in its favour. Until the cause of calculus formation everywhere in the body could be explained, probably by the chemists, doubts as to the etiology of those in the gall bladder must persist. Some predisposing causes were more common than others: repeated pregnancies, sedentary life, obesity,

all played a part. Clinically there were three types of stone—multiple small stones, iudium (few or single), giant stones. In diagnosis only one subjective symptom was of importance—pain. This pain must have special characteristics—severe, sudden in onset, referred to epigastrium, catching the breath, and on cessation leaving the patient completely well. Great advance in diagnosis was not likely till x rays demonstrated gall stones in the bladder and ducts as they did in the urinary tract. There was only one reasonable form of treatment—namely, operation—a fact not even yet sufficiently realized. When the cystic duct was patulous cholecystotomy was the best operation; this he had advocated from the earliest days, and he still did so. If the gall bladder was seriously infected it should be opened freely, the stones removed, drained, and unless the gall bladder was so obviously pathological that recovery seemed impossible it should have the benefit of the doubt. If a second operation were called for it was found that the first had increased the natural peritoneal immunity to such an extent that the consequences of the second operation were of less importance. At present he was opposed to cholecystectomy as the operation of election, and his objections were founded on the consideration of gall-bladder function and the after-results in some cases. The ducts of the body possessed a protective mechanism of considerable value to the viscera which they drained. Removal of the gall bladder often resulted in dilatation of the common duct. This disturbed the protective mechanism of a duct opening into a potentially septic area—the duodenum—and might even give rise to a form of hepatic cirrhosis.

Mr. Farquhar Macrao (Glasgow) thought that infection and stasis were the two main contributory factors in gall stones. The mode of infection was in dispute; two factors were of importance: the bacteria required to be attenuated, probably in the passage through the liver, and infection could reach the wall of the gall bladder by its lymphatics. The element of stasis was largely supplied by the drag of a mobile ascending colon. In pregnancy it was possible that the increased cholesterol in the blood and the direct pressure upwards of the uterus were active agents, though repeated pregnancies might quite well increase the ptosis. Repeated attacks of cholecystitis had been cured by fixing up the colon in the method advocated by Mr. Waugh. Practically all cases of gall-stone disease were associated with very persistent flatulent dyspepsia, and even though colic did not occur gall stones or chronic cholecystitis were commonly present. In regard to operation he remarked that all cases of cholelithiasis do not demand operation, but if definite colic occurs operation may then be urged. He was not a whole-hearted advocate of routine removal of the gall bladder; so many and varied complications could follow that operation. He would like the general practitioners to narrate their experiences of the after-results of gall-bladder operations; so far as his inquiries went the family doctor did not prefer the complete removal of the bladder to the simpler procedure of drainage.

Mr. D. P. D. Willie (Edinburgh), in speaking on the question of diagnosis, thought that by the x rays gall stones could be demonstrated if the technique were rather different from that commonly employed, and that by the use of the duodenal tube the relaxation of the sphincter of Oddi and contraction of the gall bladder were accomplished and the problem of biliary sand and chronic cholangitis simplified. Gall-stone surgery was so difficult that it should be attempted only by men of experience, as, unless the surgeon were prepared to explore fully and deal with the varied and complicated conditions found, he should leave that class of case alone. Free exposure of the parts, with accurate assessment of the full extent of the pathological process and the adoption of methods adequate for this, were the two essentials. Beside these the question of removing or leaving the gall bladder was of secondary importance.

Mr. Archibald Young (Glasgow) thought that the introductor of the dissection should be prepared to advance some sort of more or less definite substitute for the bacterial theory in etiology. Nor did it appear that the diagnosis was quite so simple as he would wish them to accept. What was required was a coherent and consistent differential diagnosis. He advocated the Ribson incision, which, if made large enough, gave adequate exposure, and if the patient were nursed in the bolt upright position gave efficient drainage. In regard to type of operation, each case must be judged on its merits. Mr. R. H. Parry (Glasgow) urged that gall-bladder cases should be sent to the surgeon after the first attack of colic, and in regard to the question of removal or drainage

the answer depended on whether the infection were confined to the bladder or was one involving the ducts as well. Mr. Novis (Bombay), Mr. Mothersole (Bolton), Mr. Handfield Jones (London), Mr. Childre (Purtonmouth), Dr. Arthur Jones (Mountain Ash), Mr. H. S. Souttar (London), Mr. Fletcher (Brighton), also contributed to the discussion, and Professor Rutherford Morison replied.

Professor Bull of Christiana followed with a most interesting operation of extrapleural thoracoplasty. He had a record of seventy-five cases, and his results justified the procedure. The indications for the operation were that the physician and surgeon working together should decide on the type of case suitable, that the operation should be performed only after failure of ordinary sanatorium treatment, including artificial pneumothorax repeatedly tried, and that the other lung should be, if not absolutely sound, nearly so. Details of the technique of the operation were given, and x -ray photographs and charts were exhibited on the screen. Perhaps the most interesting part of Professor Bull's contribution was the demonstration of the success of the operation on three patients who had come specially from Norway to Glasgow for the meeting. Sir William MacEwen invited the Section to accord Professor Bull its heartiest thanks for his noteworthy paper and demonstration.

SECTION OF DERMATOLOGY.

Wednesday, July 26th.

AFTER the President had briefly welcomed the members, Dr. Cranston Low (Edinburgh) opened a discussion on seborrhoeic dermatitis. He first referred to the discussion on the same condition at the meeting of the British Medical Association held in Cheltenham in 1901. He said that the term "seborrhoea" should only be applied to the oily discharge of the sebaceous glands, which was often associated with increased sweating or hyperhidrosis. Was this discharge due to hypertrophy or inflammation of the glands? Although bacilli were always present it was primarily an amicrobic process. Sometimes it occurred shortly after birth, and must then be acknowledged to be non-infective in origin; it was not common in childhood, but was frequent after puberty; several factors affected it. A carbohydrate diet was deleterious, as was also an excess of sugar in the food. Milk fats were worse than meat fats, because they raised the excretion of fats decomposable by bacteria. Alcohol, heat, woollen clothing, toxæmias of various kinds, and the endocrine glands were also factors which must be taken into account. On the other hand, according to Darier, "la kératose" was an anomaly of the skin and not a general disease at all, and this view was somewhat supported by Drs. Barber and Semon. Special forms of seborrhoea were: (1) true oily seborrhoea, which was always associated with acne; (2) seborrhoea capitis (a) sicca, (b) steatodes, with formation of crusts. He was unable to draw any clear opinion between the two: all conditions revealed the spore of Malassez. The connexion between seborrhoea capitis and ordinary baldness was interesting. Sabouraud connected baldness with seborrhoea oleosa, but it was more commonly associated with seborrhoea sicca. The lecturer discussed the causes of baldness, and suggested that it was much commoner in men because they wore the hair short; the wind blowing through the hair as it hung down the back was the normal stimulus to its growth. Seborrhoea corporis revealed the same organism as seborrhoea capitis, but whether it was the cause was very doubtful; the possibility of widely spread cases being due to sensitization to some protein must be considered. Some of the cases of extensive and resistant eruptions on eyebrows and beard occurring during the war might have been due to sensitization to protein or to the staphylococcus. He was inclined to think that in any case sensitization of some sort played an important part in the causation of seborrhoeic disorders.

Dr. Barber (London) said that he had been investigating the subject since 1917. Dr. MacCormac had pointed out that the seborrhoeic state was very common in the army. A distinction must be drawn between seborrhoeic dermatitis with secondary infection and eczematized impetigo. Most cases of severe mustard-gas dermatitis occurred in persons in the seborrhoeic state. These cases had gone on after the war but were now less numerous. Some of the patients had become seborrhoeic only while in the army, but others, the more severe, had been affected already while in civil life. It was difficult to define the seborrhoeic state. Excessive greasiness of the skin was a racial and familiar characteristic. There was also a pathological seborrhoeic state in which the secretion was altered as

well as increased. Alteration was the more important, for seborrhoeic dermatitis might occur in ichthyotic subjects. In acute cases there was increased acidity both of the secretions and of the urine. The resistance to the invasion of bacteria was diminished. The chief organisms were the *Staph. albus* and *aureus* and the acne bacillus, each of which produced characteristic eruptions. The best treatment was by means of autogenous vaccines. Large doses of alkalis were also recommended in less acute cases because of the diminished alkali reserve. He preferred to use this term rather than acidosis, which was used also for other conditions. The blood sugar, he found, was not as a rule much above normal, except when secondary pyogenic infections had occurred. It was highest in cases of syphilis *harbae*. The chief factors in the seborrhoeic state were: (1) faulty digestion, especially of carbohydrates, with consequent increase of acids; (2) hepatic insufficiency; (3) imperfect oxidation, lack of exercise, bad ventilation, and anaemia.

Dr. MacKenna (Liverpool) said that Dr. Barber and his colleagues were doing much to illumine an obscure subject; he did not think that the fact that acid was being eliminated proved that the alkali reserve was lowered, but he thought that Dr. Barber's later investigations had done so. He thought that the endocrine glands had something to do with every case of seborrhoeic dermatitis. He disagreed with Dr. Cranston Low as to the cause of baldness, but ascribed the earlier loss of hair in males than in females to differences in their endocrine glands. He uttered a word of caution against attaching too much importance to protein sensitization. Dr. Kenneth Wills (Bristol) desired to emphasize the infectivity of seborrhoeic dermatitis. He noticed that children who had seborrhoeic eczema were always associated with parent or nurses who had seborrhoea *sicca* of the scalp. He had seen striking instances of this in his practice. Dr. Douglas Heath (Birmingham) had also noted that large doses of alkalis improved acute seborrhoeic conditions. He also found that sulphur lotion was much improved in its action by being made up in an alkaline solution. He thought that olive oil, although a popular remedy, was highly deleterious in seborrhoea. Dr. Barber, on being recalled for his views on treatment, spoke in favour of autogenous vaccines, which he found extremely useful, notwithstanding the poor results which some dermatologists had reported from vaccine therapy. Dr. A. M. H. Gray (London) asked the meeting to define what was meant by seborrhoeic dermatitis and seborrhoeic eczema. He considered seborrhoea to be a mere excessive secretion of the glands, and he excluded conditions where there was any inflammation whatever. The term "seborrhoeic dermatitis" he applied to cases where there was some inflammation, most typically to the cases of circinate and figurate dermatitis in the centre of the chest and back. He refused to associate premature alopecia with the barber's shop and local infection, and in our present ignorance of the endocrine glands he preferred to stress the hereditary factor in these cases. Dr. Norman Walker (Edinburgh) held, on the contrary, that the local cause was responsible for the loss of hair. He believed in frequent washing of the scalp as a preventive of baldness. Moreover, he believed in the treatment of the scalp as the key of the treatment of seborrhoeic conditions, and above all, of rosacea. He also emphasized the importance of treating the oily seborrhoea of the scalp when dealing with acne vulgaris. Dr. O'Donovan (London) expressed gratitude to Dr. Cranston Low for his historical summary of the subject. He referred to the frequency of sugar excess in the blood in connexion with inveterate syphilis, but found that the exhibition of alkalis was of no therapeutic value. He had got the best results in such cases by painting them with liquid acid mercury nitrate. Dr. Murray (Glasgow) said that more treatment should be devoted to the scalps of children, and that seborrhoea of the scalp was often aggravated by working in watery solutions. Dr. Brown (Local Secretary of the Section) referred to two cases of his own in which gastric analysis had shown marked hyperacidity. Dr. Lancashire (Manchester), emphasizing the importance of preventive treatment, said that sulphur was best used as an ointment. He was disappointed with colloidal sulphur. Dr. Goodwin Tomkinson (Glasgow, Vice-President) referred to a case of seborrhoeic dermatitis associated with failure to pass an examination combined with a diet of sweetmeats.

The President then summed up the discussion. He said that the nature of seborrhoea remained obscure, but that Dr. Barber had started his researches on scientific lines. There were three possible lines of research: (1) clinical; (2) on the lines of comparative anatomy; (3) biochemical.

The study of the glands in vertebrata revealed a correlation between keratosis and sebaceous activity. Probably the sebaceous glands were not purely fat glands but "moulting" glands. For the President seborrhoea signified alteration of the colour of the skin and cessation of the keratinization of the cell associated with loss of hair. When formation of keratin was exaggerated and a true exoskeleton was formed, as in reptiles, the sebaceous glands disappeared. So they did in birds, with the exception of the uropygial gland. On the biochemical side, he considered that the alkalinity of the tissues was an important point. All cutaneous inflammations were accompanied by acidity of urine because the exudation drained away the alkalis from the blood. He also considered relations of sugar to the blood important; probably the mischief was done by one of the di- or poly-saccharides as yet undiscovered. Dr. Cranston Low in his reply said that he still adhered to his opinion that men grew bald because they cut their hair short; he was disappointed with the result of the alkaline treatment of seborrhoeic conditions. Dr. Barber also replied.

After the discussion Dr. Lancashire read a short paper on "Dermatitis urticae." He classified the disease into four types: (1) Hysterical subjects, who mutilate themselves with the idea of exciting pity and interest. (2) Those who appeared to suffer in order to please themselves and find a morbid satisfaction in the contemplation of their own infirmities. (3) Those who are victims of obsession and sudden uncontrollable impulse. (4) Those who practise the production of these lesions as a habit, comparable with nail biting. In treating these cases he, unlike many of his colleagues, found that the best course was to tell the patient that she had been found out.

SECTION OF DISEASES OF CHILDREN.

Wednesday, July 26th.

In opening the joint discussion with the Section of Physiology on the etiology of rickets, Dr. Leonard Findlay reminded his hearers of the work done on rickets by physiologists and clinicians, work in which Glasgow graduates had taken a large share. While not belittling the achievements of physiologists he thought the final battle as to the etiology of human rickets must be fought out in the clinical field. It was necessary to see how far theories of pathogenesis stood the test of clinical experience. Rickets had a definite geographical distribution and seasonal incidence. It was also, except in India, a disease of the poor. These facts must be reconciled with any theory of its origin. In his investigations into rickets Dr. Findlay had met with several perplexing facts. For instance, one child might be actively running about and yet x-ray examination showed a severe degree of deficient calcification at the growing ends of the long bones. In another case, ostensibly in consequence of some therapeutic measure, the bones showed signs of healing but the child remained helpless and disinclined to walk. This raised the question as to whether rickets was a disease which might implicate any part of the body or whether bone changes were necessarily always present. The dietetic theory of rickets was at present the most popular. Clinically the diets might be divided into three groups: prophylactic, provocative, and curative. The addition of cod-liver oil to the diet appeared to have a prophylactic effect in some cases but not in all. Certainly children brought up on diet deficient in fat did not necessarily develop rickets. The recent work of Hutcheon in India made it difficult to understand how diet could be an important factor. As regards the curative effects of cod-liver oil Dr. Helen Mackay's work showed that no improvement followed addition of fats to the diet except during the summer months. If the absence of fat-soluble A were the cause of rickets keratomalacia should be seen in many cases, but in point of fact it was very rare. Environment and general hygiene had always seemed to be factors of importance. Dr. Findlay himself was inclined to lay stress on the absence of exercise. Sunlight had a curative effect, but in the cases ascribed to lack of sunlight lack of exercise had also been present. In Iceland rickets did not occur, although there was no sun for four months in the year. Dr. Findlay concluded that rickets was not a deficiency disease. He thought it was somehow associated with confinement, but suggested that in both experimental and clinical fields the idea of rickets being an infection should be more seriously entertained and investigations undertaken with this idea in view.

Professor Mellanby (Sheffield) considered rickets as a disease accompanying growth, and due primarily to defective feeding.

A rickets-producing diet was one that contained too little of those foodstuffs responsible for proper calcification of bone, and too much of those substances responsible for the growth of tissue. In diets containing a sufficiency of calcium and phosphorus the most potent influence for procuring the calcification of bone was a vitamin having distribution and properties similar to fat-soluble A. The essential factors of a diet were interdependent, and it was no longer possible to speak of excess or deficiency in an absolute way. The amount of fat-soluble vitamin which might be sufficient in one diet might become relatively deficient if more cereal were added. Similarly, calcium might become inadequate if excess of butter or cod-liver oil were given. In his experience rickets never developed on a good diet however bad the environment, and a really bad diet would result in rickets in the most perfect surroundings. He then discussed the interaction of fat-soluble vitamin, calcium, and phosphorus, and the relation of the experiments performed on rats by various investigators to his own work on dogs. With regard to cereals, he maintained that the severity of rickets produced by a deficiency of vitamin depended, if other things were constant, on the amount of carbohydrate ratio—the more carbohydrate consumed the worse the rickets. Adding more cereal to a diet already adequate caused young animals to increase in weight from deposit of fat in the tissues and to become lethargic. Addition of fat, on the contrary, stimulated metabolism. The fat was not deposited in the tissues. It was burnt, and the animal became more lively and took more exercise. It was probable that a child's activity depended on its diet, not on its environment. It was therefore not lack of exercise but the unsuitable feeding which produced lethargy in the child and caused rickets. Dr. Mellaubay agreed with other workers as to the therapeutic effects of sunlight. He thought they might be explained by chemical changes in the skin whereby vitamin was liberated into the circulation. He was of opinion, however, that sunlight was of secondary importance and would only prevent rickets in cases that were receiving a mediocre "border-line" diet.

Dr. Robert Hutchison (London) said that he could only speak of rickets as a clinician. He was seeking the truth, which in this case appeared to be hidden very deeply at the bottom of a well. As regards the cure of rickets, clinicians had always succeeded in curing the majority of cases. Thirty years ago Dr. Cheadle had insisted on the importance of hygiene in rickets. The speaker agreed with Professor Mellaubay that the dietetic factor could not be left out of account. If cures could not be obtained by altering the diet when other conditions remained the same, then work in hospital out-patient departments would be futile. Clinicians had long recognized that deficiency of fat and protein and relative excess of carbohydrates were important factors. He thought that adding oatmeal to the diet was of advantage in rickety children. There was, however, evidently another factor in the causation of rickets of which at present we were ignorant. He thought that rickets was a metabolic disease and not a microbic infection. Workers should concentrate on the study of metabolism in rickets, as was being done by Professor Paton and his associates. Professor Noël Paton (Glasgow) said that from the practical point of view there was no evidence of the existence of any antirachitic agent in butter and milk fat. Professor Mellaubay had produced rickets in dogs on a diet of separated milk, but other factors were really involved, such as low calcium and low fat intake. The difficulty was that rickets so often underwent spontaneous improvement. He could not find any evidence that it was cured by butter. His experiments on puppies showed that those kept in the country on separated milk were free from rickets, whereas those kept in the laboratory on whole milk contracted the disease. Cod-liver oil had a curative action, but so had other agents, such as sunlight, ultra-violet rays, and fasting, and many cases were self-cured. Rickets in pigs cleared up when the salt content in the diet was altered. He had tested the infective theory by inoculation of blood and feeding with faeces, but with negative result. He concluded that we knew little more about the cause of rickets than Glisson or Soranus. He thought that workers should co-operate, avoid theories, and get to work on facts. Professor Korenchewsky (London) said that the results of his experiments agreed with those of Professor Mellaubay. Deficiency of fat-soluble A might produce either rickets or osteoporosis. The action of vitamin A on the skeleton was the result of several factors, only some of which were known at present. First, it had the property of conducting to the

normal deposition of lime salts in bone. Secondly, it was necessary to growth and normal nutrition of tissues. Thirdly, it had the power of inducing a normal state of appetite. Different individuals resisted the bad effects of deprivation of vitamin A in different degrees. The state of nutrition of the mother during pregnancy and lactation was a most important factor in the skeletal development of the offspring. Dr. J. B. Douglas Galbraith (Glasgow) gave the results of a clinical investigation carried out in different groups of children whose diets were carefully controlled. Some children were fed on a diet rich in fat, others on a diet deficient in fat, others were breast-fed. During the winter a large percentage of the children in each group developed rickets, but the percentage was slightly higher in the group on the diet rich in fats, and this group also had the disease rather more severely. Very few children developed rickets during summer. Cod-liver oil was not given, milk fat being used in all cases.

Dr. J. Sim Wallace (London) read a paper on the association of dental hypoplasia and rickets. Those well acquainted with the facts did not believe in the vitamin theory as regards teeth. The enamel was developed long before the eruption of the teeth. In feeding experiments the hypoplasia, which was thought to have been caused by the absence of vitamin, must have existed two or three months before the special feeding was begun. In rickety children there was no defect of enamel as a rule, and caries was not more frequent in them than in others. The only connexion between rickets and caries lay in the fact that excess of carbohydrates caused both. Dr. H. S. Hutchison (India) gave the result of his observations on dental caries in the Nasik district in India. Dental caries was rare among the natives, but its incidence was the same in all classes. Rickets, on the other hand, was six times as common in the upper classes, where purdah was the rule. He did not agree with Dr. Mellaubay as regards the activity of children being due to fat in the diet. The children of the poorer classes in India who received scarcely any fat were extremely active. Dr. J. B. Orr (St. Andrews) limited his remarks to one aspect of the dietary factor in rickets—namely, the mineral content of the food. The requirements of individual species varied, the ideal proportion of minerals for each species being that found in the milk. The utilization of minerals depended on the form in which they were present in the food and their relative proportions. He had repeated Dr. Mellaubay's experiments on pigs and had confirmed his results; but when he had adjusted the mineral ratio to the requirements of the animals no rickets developed, although the other factors in the diet remained the same. Dr. W. E. Elliot, M.P. (Glasgow), laid a special stress on the disturbance of balance in the diet in rickets. The mineral content was extremely important. The dietetic facts had not been as yet thoroughly investigated. It was impossible to dogmatize until they were known. Dr. Leonard Findlay replied.

SECTION OF INDUSTRIAL DISEASES AND FORENSIC MEDICINE.

Wednesday, July 26th.

PROFESSOR GLAISTER, President of the Section, in his opening address (published in full in last week's JOURNAL, p. 165) referred to the conjunction of the subjects of forensic medicine and industrial diseases in one Section and pointed out that hitherto forensic medicine had been considered chiefly from the standpoint of criminal law. From time to time the question had been openly discussed. Whether the time had now arrived for the inclusion under one group-subject of all matters which involve the application of the science of medicine to the purposes of law, such as National Health Insurance, the Compensation and Employers' Liability Acts, and those portions of public health law briefly comprised under the headings of nuisances, unsound food, and others relating to medical knowledge as applied to the law, with the title of State medicine. He was of the opinion that the time was not yet ripe for such general inclusion. The remainder of the paper was devoted to the subject of industrial diseases and compensation considered retrospectively and prospectively, including the advisability of establishing a State system of accident insurance. Professor Allison read a paper on the importance of teaching medical jurisprudence to students of medicine and law. The necessity was emphasized by the medical jurist viewing disease, accident, and death from the legal as well as the clinical standpoint, and the need for acquaintance with medical matters on the part of lawyers pointed out. A plea was made for more frequent

post-mortem examinations where the cause of death was doubtful, even though lay evidence pointing to violence was not present. Suggestions were made for more thorough teaching of the subject to students, and it was specially urged that wherever possible they should be brought into more intimate contact with actual cases.

In the discussion which followed the address Sir W. H. Willcox agreed that more attention should be devoted to forensic medicine during the student's curriculum, and also entered a plea for more frequent post-mortem examinations. Mr. J. D. Strathern, Procurator-Fiscal for Lanarkshire, was of opinion that medical jurisprudence should be a compulsory subject for examination for all law students, and advocated the desirability of more frequent discussion of medico-legal subjects by lawyers and doctors. Dr. Godfrey Carter (Sheffield) advocated that in all large cities having a medical school the work of police surgeon should be delegated to the person holding the lectureship in forensic medicine. The President and Sir Thomas Oliver also took part in the discussion.

Sir W. H. Willcox read a paper on the dangers to health produced by the use of industrial preparations of arsenic. He enumerated the commoner preparations used, and showed how these might result in poisoning of an accidental, suicidal, or homicidal type. He pointed out that there had been a large increase in the number of cases of poisoning from industrial preparations of arsenic since restrictions with regard to the sale of certain arsenical preparations of arsenic were relaxed in 1908. Illustrative cases of accidental poisoning were adduced and some recent trials for murder referred to.

Sir Thomas Oliver and Professor Glaister, who took part in the discussion, agreed with Sir William on the urgent need for further restrictions on the sale of preparations of arsenic. The Section then passed the following resolution:

The sale of arsenical preparations included under Section 2 of the 1908 Act should be limited (1) on the part of the seller to properly qualified and competent persons—namely, to registered pharmacists; and (2) on the part of the purchaser to those who have obtained a licence for the possession of such dangerous articles.

SECTION OF PHYSIOLOGY.

Wednesday, July 26th.

On Wednesday morning, July 26th, this Section (as recorded elsewhere) held a joint session with the Section of Diseases of Children for an important discussion on rickets.

In the afternoon a demonstration on rickets was given in the Physiological Institute. A large number of specimens illustrative of various aspects of the disease as occurring both in the human subject and in animals were on view. The chief exhibits were: (1) Experimental rickets (Mr. A. Watson and Professor D. Noël Patou). X-ray photographs and actual bones of normal and of rachitic puppies. Influence of various experimental conditions, chiefly dietetic. (2) Experimental rickets (Professor V. Korenchovsky). A fine series of microscopic specimens of rachitic changes in the bones of rats—mostly due to a diet deficient in vitamin. (3) Rickets in India (Dr. H. S. Hutchison and Dr. G. Stapleton). A most interesting series of photographs and skiagrams illustrating rickets in various conditions and early and late cases of rickets amongst the native population. (4) Clinical rickets (Dr. J. B. Douglas Galbraith). Skiagrams and photographs showing the progress and cure of the disease in children.

RADIOLOGY AND ELECTROLOGY.

Wednesday, July 26th.

Dr. L. A. Rowden, the President of the Section, opened the proceedings with a brief address of welcome. He prophesied an increasingly important place for radiology in the treatment of disease in the future, although, on account of the very high initial and continuing cost of apparatus, it might be that the private radiologist and electrologist would have to give way to some form of institutional provision. Dr. J. R. Kiddell (Glasgow) opened a discussion on the treatment of malignant disease by the Erlangen method of deep x-ray therapy. He recounted a very large number of cases treated by this method, with results less favourable than those reported from Germany, but still with a high average of success. In 30 per cent. of the cases all evidence of the disease had disappeared, and in 52 per cent. the benefits secured were very great in the form of relief of pain and discomfort. Dr. Douglas Webster (Middlessex Hospital) also

read a paper on the subject. The whole matter, he said, was one in which sure conclusions as yet were difficult to arrive at. A series of notable advances in x-ray instrumentation and in methods of quantitative measurement of depth radiation were being made, and these must in a short time result in a great increase in the knowledge of the subject. He was sure that some of the beneficial effects he had seen could not have been obtained with any other method of treatment. Dr. F. Herniman-Johnson drew attention to some principles which were in danger of being overlooked. Cancer treatment must always be considered, not only in relation to the malignant cells, but to the surrounding tissues and to the general state of the patient. Too much attention was apt to be paid to the single large dose—the "knock-out blow"—and not enough to the series of small doses which would often give relief for years. A number of questions were put to the readers of the papers by Dr. J. Mitchell, Dr. Gibson Graham, the President, and others. Dr. Woodburn Morison (Manchester) then read a short paper dealing with the differential diagnosis of diseases of the diaphragm, and showed x-ray views of a number of cases. Dr. F. Herniman-Johnson opened a discussion on gas inflation as an aid to x-ray diagnosis. He described the uses of peritoneal inflation, the risks of the method, and the importance of careful technique, and then turned to the subject of perirenal inflation, the method introduced by Dr. Carelli of Buenos Aires. The advantage of being able to show the complete kidney outline, together with that of the suprarenal capsule, was obvious. It would often in itself clear up a doubtful diagnosis, and when combined, as Carelli suggested, with gas inflation of the ureters and pelvis, left little to be desired in the way of x-ray demonstration. Recently, in conjunction with Dr. Ernest Young, the opener of the discussion had made some experiments upon inflating the stomach and duodenum through a fine duodenal tube. So far as the duodenum was concerned, the gas appeared to distribute itself too quickly into the small intestine to permit of useful outlining. The value of stomach inflation was that, when combined with peritoneal inflation, it enabled comparatively small changes in thickness in the anterior wall of the stomach to be recognized. Dr. J. M. Redding (London) laid stress upon the need for careful selection of cases in the method of injection of gas into the peritoneal cavity. In such selected cases the method would furnish information not to be obtained by any other means short of an exploratory laparotomy. Dr. Herniman-Johnson, in reply to the President and others, said that he regarded CO₂ as more desirable than oxygen; the only disadvantage of CO₂ was that the pictures must be taken very quickly.

SECTION OF ANAESTHETICS.

Wednesday, July 26th.

A WELL-ATTENDED meeting of the Section of Anaesthetics was held in the University Buildings on Wednesday, July 26th. The President, Dr. McCardie, in his opening address, after referring to the honour done him by choosing him as president of the Section and thanking Dr. Fairlie, the local honorary secretary, for the admirable arrangements made for the meeting, stated that he was led to believe that the official training of Glasgow medical students in the administration of anaesthetics was still in the hands of surgeons. This practice was in the best interests neither of the students nor of the patients. It was impossible for surgeons engrossed in the ever-widening field of their own activities to keep abreast of advances in the rapidly developing art of anaesthesia, much less to teach such developments. The life of a patient often depended not only on the choice of an anaesthetic but also on its method of administration. His fellow workers in Glasgow and other parts of Scotland had taken a full share in these developments, and he ventured to prophesy that this first meeting of the Section of Anaesthetics to be held in Scotland would be the precursor of many other meetings in her cities. Dr. David Lamb (Glasgow) then read his paper on "Bronchopulmonary complications following operations under anaesthesia." Whilst all Glasgow anaesthetists used ether freely, as well as chloroform, in their work, the students were still taught that whilst a few deaths occurred on the table from chloroform, far more occurred after the operation from pulmonary troubles and heart failure when ether was used. The number of fatalities occurring annually in this city from chloroform in the hands of comparatively inexperienced anaesthetists would probably surprise, if not startle, the adherents of this old doctrine. In regard to the frequency of

these complications, statistics were of little value unless based upon careful personal observation of all cases, and unless discriminating between clean and septic cases and between those beginning in the first twenty-four or forty-eight hours after operation and those occurring later on. The latter were almost always associated with sepsis. The most important contributory factor in the causation of broncho-pulmonary complication was the presence of more or less recent catarrhal affections of the upper air passages of the patient prior to the operation. Next in importance was exposure to chill before, during, or after operation, though there were other contributory factors, including aspiration of infective organisms from the mouth and throat ("aspiration" pneumonias). The later pulmonary affections were practically all septic in origin. With regard to the part played by the anaesthetic, opinion in this country and abroad varied considerably, but the general consensus of opinion was that prolonged administration alone (more especially of concentrated vapour of ether) gave rise, by direct irritation or by chilling due to evaporation, to any real danger. The vapour of ether, and of chloroform to a very much less degree, was an irritant to the lining membrane of the upper air passages and bronchi, but unless unskillfully administered hardly ever enough to set up a purely irritant bronchitis or broncho-pneumonia like that caused by poison gases during the war. But where the resistance of those tissues was weakened by chill or lowered vitality, or the presence of a mild catarrhal condition, or both together, this comparatively mild irritant action, more especially of ether, might act as the "last straw." For prevention Dr. Lamb advocated the employment of expert anaesthetists, who would be more likely to avoid the use of a too concentrated vapour and the administration of ether in cases in which its use, prolonged or otherwise, was contra-indicated. He also advised preliminary administration of atropine and avoidance of ether in "catarrhal" cases, lateral position of head when possible after operation, especially in mouth cases, to prevent aspiration troubles, avoidance of tight bandaging in heart and abdominal cases, and washing out the stomach prior to operations in "obstruction" cases.

The paper gave rise to an interesting discussion in which the following took part: Dr. Dickinson Berry (London), Dr. Flemming (Bristol), Dr. Paton Boyd (Glasgow), Mr. Herbert Paterson (London), Dr. Featherstone (Birmingham), Dr. Pinson (Manchester), Dr. Johnson (Aberdeen), Dr. Piuto-Leito (London), Dr. Fairlie (Glasgow), Dr. Barras (Glasgow), and Dr. Adams (Birmingham). The discussion was wound up by the President, who reviewed the various remarks made by the speakers, and commented upon them and upon the excellent paper contributed by Dr. Adams. On the invitation of the President, the members of the Section then met together at lunch in the Students' Union. A less formal meeting followed at which Dr. Flemming (Bristol) read his paper on "Different effects produced by exposing tissues to various concentrations of anaesthetic vapour," followed by a demonstration of these effects, illustrated by the microscope, photographs, and living plants. Subsequently Dr. Featherstone demonstrated his new airway, and Dr. Pinson his "bomb" apparatus for the administration of ether vapour.

SECTION OF ANATOMY.

Friday, July 28th.

THE PRESIDENT, Professor Alexander Macphail (London), said that the British Medical Association had always identified itself with scientific work, and had included anatomy in its list of subjects for discussion whenever possible. He emphasized the value of anatomy to those in practice or working in other scientific fields. On the other hand, anatomists derived great benefit by contact with the practising profession. He wished to pay a tribute to the man who was his teacher in this University and under whom he had been senior demonstrator. Professor Cleland was a giant both in intellect and stature. He thought he would be interpreting the wishes of the Section if he asked the secretaries to transmit to Professor Cleland a message expressing the esteem, high regard, and affection which they felt towards him. Professor Macphail then went on to discuss the administration of the Anatomy Act, and the measures he had taken to obtain sufficient anatomical material for teaching. Only unclaimed bodies were asked for, and he deprecated any attempt to bring about any form of compulsion in the disposal of bodies. He thought that when those in charge of unclaimed bodies understood what

they were wanted for no difficulty would be found in obtaining sufficient material. Professor J. C. Brash (Birmingham), discussing the relation of the ureters to the vagina, explained his method of dissection, which preserved this relation and also marked out the trigone in relation to the vagina. In the course of this work he had discovered several interesting facts. The relation of the last portion of the ureter to the vagina was variable. There was usually a portion of the ureter in front of the vagina lying for a short distance in the connective tissue between the vagina and bladder and then in the wall of the bladder itself. The vagina and bladder were usually not symmetrically related to each other. The result was an increase of this portion of the ureter on one side and a corresponding decrease on the other. In the majority of specimens examined the left ureter had the closer relation to the vagina and was occasionally found crossing the middle line of the vagina; it was therefore in a position of greater danger than the right. He explained the asymmetry of the uterus as due to pressure from coils of intestine distended with meconium during the latter part of intrauterine life.

Dr. Alfred Pinoy (Birmingham) discussed the naked-eye anatomy of the bone marrow with age changes, and gave the results of examination of the bone marrow in 1,700 necropsies. Dr. J. M. Woodburn Morison described the teaching of anatomy by radiology in the anatomy department in Manchester, and outlined his scheme of radiological demonstrations to anatomy students. He explained how the structure and growth of bones, the development of epiphyses, and the movements of the heart and intestines could be studied by this method. Research students were also enabled to use the x-ray apparatus for their work.

In his paper on the structures of the vertebrate head Dr. W. B. Primrose set out to show that the structure of the vertebrate head was based upon the first metameric segment of the body with which was combined an unsegmented structure, the face. Four different skeletons appeared during development, but although morphologically distinct they were not separable anatomically. They were: (1) The sclerotome skeleton, which was first formed at a time when the somatic or body wall mesoderm became segmented for the purpose of acting upon the segmented hydrostatic or water skeleton contained in the coelomic sacs of the Annelida. The hydrostatic skeleton disappeared, but the septa separating the coelomic compartments remained to give attachment to the segmented body wall muscles and, in fishes, became the sclerotomes. From the sclerotomes were developed two sets of arches, the neural and the visceral. In the head the sclerotome skeleton was represented by one neural arch—the occipital, and one visceral arch—the hyoid. (2) The axial skeleton, which was developed from the notochord. It formed the basi-sphenoid and the basi-occipital. (3) The splanchnic skeleton, which appeared when chordate animals evolved special respiratory organs. It was represented by the gill bars in fishes and the laryngeal, tracheal, and bronchial cartilages in pulmoniferous animals. In man it also formed the greater cornu of the hyoid. (4) The facial skeleton, which was evolved in connexion with the organs of special sense, with a supplement in the form of membrane bone to support the face. The existence of this skeleton was determined by the ectoderm in the form of sense organs, brain, teeth, and general skin covering, and as none of these structures was segmented, neither was the skeleton which supported them. The author then explained the relation of the myotome, somatopleuric, segmental blood vessels, gut derivations, and ectoderm (with special regard to the cranial nerves) to the head segment and traced the development of each. A simple metameric segment was the morphological basis of the vertebrate head, but a condition of extreme specialization had been reached during evolution.

Dr. W. K. Connell's paper on the form of the palate in childhood was based on the impression taken in plasticine of the upper dental arcade in over a thousand children. The variations in shape of the arch were studied in normal and pathological states, as also the alterations which took place during growth and the relation of the size of the arch to the state of general development of the child. Nine principal shapes were found in normal children. Curiously enough, in children with adenoids no narrowing of the arch had been found. During growth the palate became actually narrower from 12 to 14. No relation had been found between size of palate and size and state of development of the child. Dr. John T. Hunter (Sydney), in discussing intestinal diverticulum with retroposition of the

transverso colon, showed drawings of the viscera of a child seven days old who had a large cyst in the mesentery. The cyst was attributed to the closing off of a diverticulum arising in the duodenum during development. The abnormal position of the colon was explained by the fact that the proximal part of the gut was bound down by the cyst and could not assume its proper position during development.

SECTION OF LARYNGOLOGY.

Thursday, July 27th.

THE discussion on the symptoms of oesophageal disease and their differential diagnosis was opened by Dr. D. R. Paterson (Cardiff) and Mr. W. G. Howarth (London). Dr. Paterson gave a survey of the symptoms connected with the more common affections of the upper opening of the oesophagus, whilst Mr. Howarth dealt mainly with the lower half of the oesophagus. The recent methods of diagnosis were described, the technique of using the fluoroscopic screen being dealt with in detail. Dr. Brown Kelly (Glasgow), in discussing these papers, described in detail his observations on cardiospasm and achalasia. Dr. William Hill (London) described primary spasm as an extra-metropolitan disease, never seen in London. He described his observations and experiments on the physiology of the cardiac orifice and the hiatus in the diaphragm. Dr. Ivy McKenzie (Glasgow) spoke of the problem of spasm at either end of the oesophagus. Sir William Milligan (Manchester) expressed the opinion that cardiospasm was due to spasmodic action of the left crus of the diaphragm, and related some experiments which confirmed that view. Dr. W. S. Syme (Glasgow) described a case of spasm of lower end of the oesophagus well above the opening through the diaphragm. Sir St. Clair Thomson (London) supported the views of Dr. William Hill. He advocated the formation of a school for the teaching of oesophagoscopy. Dr. James Adam mentioned a case of malignant disease of the hypopharynx that lasted fifteen years.

Mr. A. J. Wright (Bristol) read a paper on congenital choanal occlusion in two members of one family. Sir St. Clair Thomson related a case in which the obstruction was unilateral and the infant could only be suckled lying on the same side. The paper was also discussed by Dr. Young (Glasgow), Dr. Syme (Glasgow), and Dr. Hutchison (Brighton). Dr. H. H. Forbes read a paper on the present position of the use of radium in the treatment of cancer of the larynx and oesophagus. This was discussed by Dr. William Hill, who insisted on the importance of radiating the whole stricture in cases of malignant disease of the oesophagus. Sir William Milligan, who had had access to a large quantity of radium in Manchester, had on the whole been disappointed with the results up to the present time. He gave an account of his experience of the usefulness and limitations of this form of treatment. Sir St. Clair Thomson protested against the use of radium in operable cases.

SECTION OF OTOTOLOGY.

Wednesday, July 26th.

THE discussion on the diagnosis and treatment of septal sinus thrombosis was opened by Sir William Milligan, who dealt in detail with the diagnosis. The importance of early diagnosis and the danger of waiting for classical signs and symptoms to appear was urged, because of the much greater chance of recovery given by early operation. The anatomical conditions in which sinus thrombosis is more likely to occur were also described. Mr. Colledge followed with a paper on difficulties in dealing with such cases; he referred to some special points in the diagnosis, and especially the treatment, with some illustrative cases. In the discussion on these papers Dr. Ritchie Rodger confined his remarks to the cavernous sinus, referring to several illustrative cases. Dr. Mygind (Copenhagen) gave his experience of 141 cases, and advised exploratory operation in cases of doubt and microscopic examination of the sinus wall. He gave interesting statistics of his cases and concluded that ligation of the jugular had little or no influence in determining recovery. Dr. William Hill advocated free removal of bone in doubtful cases in order to expose adequately the sinus. He dealt with the great difficulty in deciding whether the sinus was thrombosed, and if so in what portion.

Dr. Dan McKenzie emphasized the importance of early diagnosis and the harmlessness of early exploratory operation. He advised ligation of the jugular in every case. Mr. Muecke

(London) referred to 117 cases operated on by Mr. Hunter Tod and himself. He advised ligation of the jugular in every case, combined with the administration of anti-streptococcal serum. Sir James Dundas Grant opposed the ligation of the jugular as a routine procedure, and gave his opinion as to the indications. Dr. Andrew Wyllie (London) advised injections of corrosive sublimate in cases of septicaemia. He referred to the difficulty of knowing in some cases which ear was at fault. Dr. Syme (Glasgow) mentioned an instance of spontaneous cure, the case having been mistaken for puerperal septicaemia some years previously to a radical mastoid operation. Dr. Douglas Guthrie (Edinburgh) referred to unilateral perspiration as an important symptom. Dr. Albert Gray urged the importance of avoiding the slightest injury to the exposed lateral sinus and the use of antiseptics, especially eusol. Dr. J. S. Fraser and Dr. Stephen Young read a paper entitled "Is it worth while to remove antral polypi?" This paper was discussed by Sir James Dundas Grant, Dr. Ridout (Portsmouth), Sir William Milligan, Dr. Mygind, and Mr. Frank Wilson (Newcastle).

At the afternoon sitting Dr. Holger Mygind read a paper on benign forms of otogenic meningitis. This paper was based upon the observation of 210 cases of otogenic meningitis observed in Copenhagen during the last seventeen years. Special reference was made to the examination and characteristics of the cerebro-spinal fluid in this class of cases. The paper ended with a short description of the operative measures required for these conditions, especially the indications for opening the labyrinth.

SECTION OF TUBERCULOSIS.

Thursday, July 27th.

THE PRESIDENT, Sir Robert Philip, in his opening address dealt with the administrative advances which had been made in the control of tuberculosis since the date of the last meeting of the Association in Glasgow in 1883. Tracing the decline in the death rate since that date, he pointed out that the rate had declined 48 per cent. in England and 53 per cent. in Scotland—that is, the diminution had been proceeding more rapidly in the latter country. A discussion on "The clinical differentiation of pulmonary tuberculosis from other respiratory affections" was opened by Dr. E. Rist (Paris), who dealt with the changes which had taken place, mainly as a result of experiences during the war, in our theoretical and practical knowledge of tuberculosis. The necessities of war had put before us the duty of well-founded, uncompromising decision in matters of diagnosis, and for this medical officers were not well prepared in the early days of the war. Mistaken diagnoses were all too numerous. Dr. Rist gave examples from his own experience at a tuberculosis clearing station in France and at the Laennec Hospital in Paris. At the former a diagnosis of tuberculosis previously made was found to be justified in only 27 per cent. of cases, and at the latter 82 per cent. were found not to be tuberculous. After quoting other figures Dr. Rist dealt in detail with various diagnostic methods. Tuberculin skin reactions could only be regarded as evidence of infection and not of disease. Further, it must be admitted that the individual's whom the von Pirquet test discovered were more protected against subsequent tuberculous disease than were the non-infected. A high place must be given to the x rays as aiding differential diagnosis. If used in association with physical examinations they were of great value to the clinician. Their use had enriched our knowledge of chest diseases, and modified our views of the practical value of other methods of physical examination. Methods of detecting tubercle bacilli in the sputum had improved also. Dr. Rist then dealt with the commoner diseases likely to be mistaken for pulmonary tuberculosis—for example, (1) diseases of the cardio-vascular apparatus; (2) non-tuberculous diseases of the lungs; (3) morbid conditions of the upper respiratory passages, which were probably the most common sources of error in diagnosis—indeed, over 50 per cent. of the cases examined at the tuberculosis clearing station belonged to this group.

Professor S. Lyle Cummins (Cardiff), in dealing with his own experience, pointed out the value of studies in vital capacity such as had been recently made by Professor Dreyer and Dr. Charles Cameron. He also hoped that serological tests would in time assist in diagnosis of active from inactive lesions. Dr. Marcus Paterson (London) referred to the great difficulty of distinguishing, in many cases, active from inactive tuberculosis. Some test for this was much needed. He gave

examples of erroneous diagnosis which were still too frequent, and agreed with Dr. Rist that a single positive spit in the midst of a series of negative spits was of little significance. Dr. Ian Struthers Stewart also considered that diseases of the upper air passages were often mistaken for tuberculosis. Dr. James Crockett was inclined to think that much tuberculosis was overlooked and erroneously diagnosed. Dr. A. Hoppo Gosse (London) gave an important contribution—the results of the recent work by Dr. A. L. Punch and himself—on serological diagnosis. In his hands, using living bacilli as antigen, this test promised great assistance in detection of activity, with very important practical results. Dr. Forgnus Hewat (Edinburgh), Dr. C. Muthu (Moudip Hills Sanatorium), Dr. Lawson (Tor-na-Dec), Dr. MacGregor (Glasgow), Dr. Prest (Ayrshire), and Dr. Gillies (Australia), also took part in the discussion.

Dr. James Taylor (Glasgow) read a paper on "Some aspects of the treatment of surgical tuberculosis," in which he gave his experience as visiting surgeon to the Tuberculosis Hospital of Glasgow Corporation at Robroyston, where there is accommodation for 300 patients with surgical tuberculosis. The general treatment is based on that of Dr. Rollier of Leysin, with modifications appropriate to differences in climate. The speaker considered that rapidity of cure depended very greatly on climate—that is, insulation—and he was unable to get the phenomenal results obtained by Dr. Rollier, which enabled more conservative methods to be adopted. While the treatment of surgical tuberculosis must be essentially conservative, in hospitals with the most favourable climatic conditions operative treatment combined with general treatment would give the most speedy, though perhaps slightly less perfect, results. Some results of specific treatment of cold abscesses and sinuses were given. It was difficult to prevent sinus formation, especially during the winter months. Cold abscesses were treated by repeated aspiration with a measure of success. Some who did not respond to this were treated by open operation, with careful surgical technique, and the wound sutured. This was successful in one-third of the cases. The use of modifying fluids had given the best results in cold abscesses. Calot's fluid No. 1 gave the best results, though sometimes naphthol-camphor was used successfully. Dr. Taylor referred to the good results of deep x-ray therapy in massive cervical glands, as carried out by Dr. Henderson, radiologist to the hospital. Extreme care was needed in applying antispylilitic treatment to patients with a positive Wassermann reaction and a definite tuberculous lesion.

SECTION OF OPHTHALMOLOGY.

Wednesday, July 26th.

At the opening of the first session on Wednesday, July 26th, the President, Mr. A. S. Percival, said that he considered it a high honour that he should be chosen to be President of this Section in so great a university city as Glasgow, and he believed that their proceedings would be worthy of the occasion.

The subject for discussion, "The etiology of optic atrophy," was introduced in a paper on the clinical side by Dr. C. O. Hawthorne of London, followed by Mr. J. Hogarth Pringle of Glasgow, who dealt with the more surgical aspects of the conditions responsible for the atrophy, and by Dr. H. M. Traquair of Edinburgh, who considered chiefly the finer points of diagnosis to be obtained by perimetry. Messrs. MacCallan (Cairo), Percival Hay (Sheffield), Webster Fox (Philadelphia), Bishop Harman (London), Grey Clegg (Manchester), Inglis Pollock (Glasgow), J. C. Douglas (New South Wales), J. A. Wilson (Glasgow), and Thomas H. Bickerton (Liverpool) continued the discussion, which was replied to by Dr. Pringle. A paper on the "Relations of the optic nerve to the sphenoidal and posterior ethmoidal sinuses" was read by Dr. Gavin Young of Glasgow, and specimens illustrating the relations shown. Mr. A. F. MacCallan (Cairo) read a paper on "Ophthalmic progress in Egypt," which was commented upon by Dr. M. A. el Kattan of Cairo and the President. Dr. Wellwood Ferguson of Glasgow read a paper on "The state of the cerebro-spinal fluid in disease of the fundus" and Dr. T. Stewart Barrie's paper on "Monocular and binocular vision," which was discussed by Mr. Bishop Harman (London). Mr. Percival Hay (Sheffield), and Dr. John Rowan (Glasgow). A paper by Dr. W. B. Inglis Pollock of Glasgow, on the "Open treatment in eye operations," completed the proceedings for the day.

Reviews.

THE ENGLISH PRISON SYSTEM.

Two books on the English prison system have recently appeared—the one by SIDNEY and BEATRICE WEBB, dealing nominally with English prisons under local government, but in effect with the English prison system up to date; the other, by STEPHEN HOBHOUSE, M.A., and A. FENNER BROCKWAY, devoted wholly to the consideration of English prisons to-day. The preface printed in the first-named volume, and intended as an introduction to both works, occupies about seventy pages and is written by Mr. BERNARD SHAW. From Mr. Shaw's first sentence, telling the reader of the right spirit in which these books should be read, it is easy to infer at once the uncritical spirit in which the books have been written.

Mr. Shaw assumes at the outset that the authors have established the fact that "imprisonment as it exists to-day is a worse crime than any of those committed by its victims," and advises all would-be "reformers" who hold that "imprisonment is a necessary and beneficent public institution" not to read these books, but to go about their own business. He adds that such reformers have in the past converted the old common gaol "into that diabolical den of torment, mischief, and damnation, the modern model prison." Similarly the joint authors of the book entitled *English Prisons under Local Government*,¹ holding that imprisonment as a punishment for crime is unjustifiable, devote only twenty pages of their Epilogue to a slight sketch of constructive reform of penological methods, adding "that, when all is said and done, it is probably quite impossible to make a good job of the incarceration of a human being in the most enlightened of dungeons." Again, the compilers and writers of the larger book called *English Prisons To-day*,² both having been imprisoned themselves as "conscientious objectors," make it abundantly clear in their Concluding Chapter of less than half a dozen pages that they condemn not only imprisonment as a punishment for crime; but also, in effect, any "punishment" for crime at all. Aeneas this concluding chapter it may be noted that it mainly consists of an abbreviated repetition of many previous arguments on one side only of the long controversy regarding the State's right to punish law-breakers, and in an implied, if not expressed, assumption that all crime should be regarded as curable, or at least tractable, disease, and treated otherwise than by deprivation of liberty.

These things being so, it follows that serious criticism of the essence of these books should be devoted to what seems to underlie the conclusions and assumptions of their writers, and that this method would involve several fundamental questions of social, psychological, political, legal, and even expedient import. It is equally clear that no one who does not accept the basic dogma of the mortal sinfulness and futility of the institution of penal imprisonment can possibly undertake to controvert that dogma seriously within the limits of any periodical, least of all a weekly journal. As I am such a person, I must therefore confine myself mainly to some short remarks on the constitution of the Prison System Enquiry Committee which produced the report now published under the name of *English Prisons To-day*;³ on the nature of the evidence chosen by them as the apparent basis of their conclusions; and on only a very few of the fallacious arguments used by the writers of both volumes, among whom Mr. Shaw has a conspicuous place.

1. It is stated in the summary of the Report which Mr. Brockway, the secretary of the Enquiry Committee, has provided as a possible assistance to reviewers, that the membership of the Committee "is representative of the various schools of political thought." This statement may be accurate if the word "political" be intended merely to connote the thought of the officially recognized political parties only; but be this as it may, even a superficial glance at the names of the members of the Committee will detect that schools of thought which differ from the views promulgated in the Report on the main subjects are not represented at all. The Committee was plainly appointed to arrive at certain

¹ *English Prisons under Local Government*. By Sidney and Beatrice Webb; with Preface by Bernard Shaw. London: Longmans, Green, and Co. 1922. (Demy 8vo, pp. lxxiii + 251. 15s. net.)

² *English Prisons To-day*. Being the Report of the Prison System Enquiry Committee. Edited by Stephen Hobhouse, M.A., and A. Fenner Brockway. London: Longmans, Green, and Co. 1922. (Demy 8vo, pp. lviii + 728; 4 illustrations. 25s. net.)

conclusions, and therefore, quite logically, sought out only the evidence which was appropriate to their end. In the Foreword to the Report, but not in the Summary, it is stated that this inquiry was established by the Executive of the Labour Research Department, but it does not seem clear whether the possible implication that this appointment had a political origin was intended, or whether the Committee was virtually autogenous.

2. The Committee complain that they failed to acquire the information they wanted from the Home Office and the Prison Commissioners, but that they had considerable success from making inquiries for information from fifty members of the prisons staff—for example, chaplains (C. of E. and R.C.), visiting ministers (denominational), medical officers and warders of different grades, etc. They do not state what proportion among these were ex-officers. They add, however, that they believe they have collected substantially accurate information about every phase of the prison system. The genuine nature of their belief need not be doubted, but there is plenty of room to question the accuracy of their information.

3. As to evidence collected from 290 ex-prisoners it is stated in the Report itself, but not in the Summary prepared for purposes of the press, that among these ex-prisoners were "a large number of men and women who had been sentenced to imprisonment (mostly for terms of hard labour) for political offences, but it included also a number of ex-prisoners committed for criminal offences who had had experience of both local and convict prisons." The number of the "political" prisoners is not stated, though it is said to be "large." This justifies the inference that either by failure to find many "criminal" witnesses or by the readiness of the "politicals" to give evidence the net result of the testimony as a whole was likely to be strongly biased. In this context the following short quotations from a very long answer by a "political" prisoner to a "mental questionnaire" submitted to him may be regarded as significant. Among the innumerable effects on his mind, which he seemingly attributes to the prison life, he says: "I wrote more and perhaps better poetry than I had ever done before"; and, in another place, he says that he "entered prison accepting the oblique teaching of Christ and left it an agnostic," and adds, "many other conscientious objectors like myself came out agnostics who had entered with a definite belief in God."

4. Mr. Shaw's doctrine that imprisonment neither deters nor reforms, but manufactures criminals, seems to rest on the fact that large numbers of prisoners return frequently to prison. He ignores the fact that there is considerable evidence to show that about two thirds of once-committed prisoners do not return at all. It might therefore be more reasonable to infer that imprisonment can be an effective deterrent from continuance in crime, and also that the mere existence of prisons as penal institutions may prevent innumerable potential law-breakers from taking any risk of getting into them than to accept, or still less act upon, the logical method of Mr. Shaw. At any rate it is certain that in the prisons of to-day the mere loss of liberty constitutes by far the greatest element in the punishment of imprisonment; and that although among the class of prisoners described as political, as well as among some others, the loss of liberty as well as other deprivations must be felt more keenly than by the majority of prisoners, there are many more who suffer only from the want of freedom.

Any conceivable and effective substitute for imprisonment that would not involve the loss of the law-breaker's liberty would be welcomed by everybody; but no approximation to such a scheme has yet been even adumbrated. This is by no means to say that further modifications in the administration of justice cannot be made on the existing lines for preventing some offenders from being committed to prison at all, or that no more improvements are possible in the prison regulations themselves. There are, in fact, many desirable improvements which would readily be made were sufficient funds obtainable.

5. Mr. Shaw's method of reasoning in his endeavours to establish a point is well illustrated by the following example. He refers to the Lombrosian doctrine of a "criminal type," which he describes as teaching that criminals are not responsible for their actions, and therefore should not be punished for them. He proceeds to state that "the prison authorities saw their occupations threatened and so denied the Lombrosian doctrine"; and he then insists that if there is no criminal type there is a prison type manufactured in prison by the prison system. For this statement he gives no

proof whatever, adducing as evidence only an irrelevant passage from a publication which is quite unconcerned with crime or prisoners.

After much attention to this familiar assertion, made very frequently at intervals for many years by persons who have visited prisons but once or perhaps twice, I can positively contradict Mr. Shaw's baseless announcement that "the simple truth is that the typical criminal is a normal man when he first enters a prison and develops the 'type' during his imprisonment" by the simple statement that such a type has no existence.

It may be gathered with sufficient clearness from the above notes that the authors of the Report of the Committee of Enquiry, and the rest of the investigators, must have started their work with certain postulates on ethical, social, and other questions which could not fail to influence them while collecting evidence and drawing up their conclusions for publication; and therefore the real matters at issue between the writers of these books and any critic or reviewer of them who cannot accept their initial assumptions are far too wide and fundamental for detailed treatment here. Such treatment of even the few pages of which the concluding chapter of *English Prisons To-day* consists would fill the space of a very lengthy pamphlet at least.

It is not to be denied that some possibly good result might conceivably be obtained if the scheme, slightly sketched in these books, for a practical conversion of prisons into educational and hygienic establishments devoted to the physical and mental examination and treatment of each individual law-breaker sent to them were realized; but considering that about 80 per cent. of committals are for only one month or less the question immediately arises whether the great expenditure thus involved might not be far more fruitfully devoted to the interests of better and wider education than obtains at present for the youth of the community at large. And, as we have already seen, all the five writers of these books are at one in their declaration that no good thing can come out of any form of incarceration.

H. BRYAN DONKIN.

THE HISTORY OF CARDIOLOGY.

In *The Heart: Old and New Views*,³ by Dr. H. L. FLINT, we have a presentation of the growth of knowledge of the heart and its functions, from the remote past to the present. The author's object has been to give a consecutive history, to link together the more or less isolated data, and to draw a clear picture. Dr. Flint has succeeded in doing this in a pleasing and satisfactory manner. He takes his readers back to 4000 B.C., when there appears to have been no clear distinction made between the heart and the liver. Later, in 1500 B.C., the soul in the form of a manikin was believed to dwell in the heart. It was about this date that an Egyptian wrote that the vessels lead from the heart to the body.

The book before us is divided into two parts. The former deals first with the Hippocratic period, and traces the gradual growth of knowledge through the Galenic and the Vesalian, ending with an account of the discovery of the circulation by William Harvey. This is perhaps the most interesting section in the book. Though short, the story of Harvey's gradual perception of the vital facts of the circulation is admirably told. Stephen Hales is rightly credited with the first substantial advance in the physiology of the circulation since the time of Harvey, and from then on the outstanding landmarks of progress are noted.

The second and larger part is devoted to a concise description of instruments and methods. Here, as in Part I, the gradual advance in knowledge is recorded, beginning in 1861 with the method of Chauveau and Marey, by which they recorded the intracardiac pressure in the various chambers of the heart. The gradual development of the instruments for recording blood pressure is related, and there is an account of the sphygmograph, polygraph, and the electro-cardiograph. Normal records from these instruments are analysed and explained.

A section is usefully devoted to the five functions of the myocardium, first clearly described by Gaskell; then follows an account of the cardiac irregularities and abnormal rhythms, which is fully illustrated with characteristic records.

Lewys at

³ *The Heart: Old and New Views*. By H. L. Flint, M.D. London: H. K. Lewis and Co., Ltd. 1921. (Demy 8vo, pp. 183; 63 plates. 15s. net.)

tanco of such a bruit, both in prognosis and treatment, absence of any evidence of heart disease.

Clifford Allbutt, in an introductory preface, expresses appreciation both of the matter of the book and the manner of its presentation.

PAPERS FROM THE MAYO FOUNDATION.

The first annual volume of *Papers from the Mayo Foundation for Medical Education and Research and the Medical School* covers the period 1915-20 of the Graduate School of the University of Minnesota and represents research work put out, principally, by the younger members of the staff, the Mayo clinic and in the hospitals controlled by the medical school of the University of Minnesota. Nearly all the papers in this collection, which must be distinguished from the familiar *Collected Papers of the Mayo Clinic* now in double volumes, were originally theses for the degree of Master of Science or Doctor of Philosophy in various pre-clinical or clinical subjects.

The articles, sixty-five in number, are arranged under the headings of alimentary tract, uro-genital organs, ductless glands, circulatory organs, blood, skin and syphilis, the nervous system, the head, trunk, and extremities, metabolism, general, the last including papers on bacteriology, physiology, and the effects of inanition on albino rats. Some papers are published in full, others in abstract only, but in all cases being given to the periodical in which they originally appeared.

The field covered is very extensive, as has already been stated, and the articles treat aspects of the various sciences ancillary to medicine; this may be shown by mentioning a few of the subjects: the geotropism of the marine mollusc (*Littorina littorea*), growth of the human foetus (several papers dealing with various parts of the body), the development of the suprapericardial (post-brachial, ultimo-brachial) in *Squalus acanthias*, and the development of the liver pancreas in *Amblystoma*. There are also many papers dealing with ordinary medical practice, such as carcinoma of the prostate, the treatment of chronic empyema, and gastric cancer. Pathology receives due attention both from the point of view of morbid anatomy and in its experimental aspects: examples of the former are papers on the histology of carcinoma in the islets of Langerhans by E. J. Jan, and a study of 256 cases of squamous-celled epidermoid of the skin by A. C. Broders; and of the latter by J. W. Harrington's paper on the effect on the kidney of various surgical procedures, such as double ligation and section of the ureter and decapsulation of the kidney; it is based on experiments on the dog because of the similarity of the anatomy, and especially of the physiology, to those of man. The volume is a record of enviable activity. As it is edited by Mrs. M. H. Mollish, whose work in this capacity for the *Collected Papers of the Mayo Clinic* is so well known, there is no need to say that it is admirably brought out.

NOTES ON BOOKS.

In fulfilment of a promise to the late Sir Lauder Brunton, ERNEST HART has published a booklet for the help of cooks and cooks in the preparation of food for the sick. At the outset we may say that it is a pity that the authoress has set forth in her opening pages a list of "bidden" foods, and at the same time laid down in general terms "permissible foods." The modern therapy of glycosuria and diabetes does not follow such simple rules. Nevertheless, the collection of recipes is well calculated to enable a skilful cook to convert a bare catalogue of foodstuffs prescribed by a physician for an individual case into sufficiently appetizing dishes to make a strict regimen not merely tolerable but even enjoyable to the eye and the palate. Colonel Waters in his work on *Diabetes* (reviewed on June 24th, 1922, p. 1000) asked: "It is of little moment in what form the various sugars are given." Mrs. Hart's little book serves to remind us that to the patient there may be a vast difference between a physiological food-value cooked in a dixie by the domestic cook, or placed on the table by a disciple of the *à-savarin*.

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE.

The first session of the third International Congress of the History of Medicine was held at the Royal Society of Medicine on July 18th, the President, Dr. SINGER, in the chair. The opening proceedings on July 17th were reported in our issue of July 22nd.

Plague.

Dr. TRICOT-ROYER (Antwerp) gave an account of the orders of the magistrate of Antwerp against the spread of the plague in the seventeenth century. In 1661, by the orders of the local authorities, the canals were constructed so that the contaminated water from the southern canals should not mingle with that of those of the northern district of Horebals. Dr. Tricot-Royer described the method of filtering the water, and then gave a description of the lazaret-house of Horebals and the chapel dedicated to St. John the Baptist, patron saint of lepers, in the grounds. Twice yearly pilgrims visited the chapel, bringing gifts to the lepers.

Professor JEANSELME sent a paper in which he argued that in the history of the Byzantine Empire the climatic conditions were often the cause of plague; when the Greeks lost Egypt to the Arabs they were deprived of the greater part of their corn, so that famine arose and the people more readily succumbed to the plague. He attributed the distribution of disease to the fact that the rats, carriers of the plague, finding the granaries empty, left the sewers and subterranean areas and came into closer contact with man.

Dr. WICKERSHEIMER (Strasbourg) described the visitation of the black plague to Strasbourg in 1349 and gave an account of the precautions taken. According to a contemporary account the disease attacked the population in the following manner: on the first day they were seized with sickness, the next day with shivering and fever, and the third day the glands appeared under the arms and on the legs. He gave an account of the various remedies given and also the carrying of musk, wormwood, and other aromatic substances as preventives. The death roll in Strasbourg from this visitation amounted to about 16,000 out of a probable population of 30,000.

Dr. NEVEU (Paris) then gave an account of plague in Tuscany in 1349, and described the terrible outbreak during the Middle Ages, when so little of rational treatment.

Greek Medicine.

Dr. CAVVADIAS (Greece) read a communication on the cult of Asklepios and medical science. He recognized two divisions of Greek medicine: the medicine of observation, that appealing to intelligence, what might be called rational or true medicine; and mystic medicine, faith healing, the power of suggestion acting with the hidden forces of the soul within ourselves—the cult of medicine shown in the religious medicine of the Greco-Roman period, of the Middle Ages, and in the Christian Science of to-day. The Greeks had their gods to cure disease and avert death, and of these Apollo, discoverer of medicine and physician to all Olympians, was the head. This alliance of the god of art and music with medicine showed that these three branches were considered by the early Greeks the foremost in the art of living. Asklepios, in some legends described as a son of Apollo, was not originally one of the Pantheon. He was a king with a great skill in medicine; he was deified and became foremost god of medicine. Though his followers practised their art by the temples of Asklepios they were not priests. For some time they passed their teachings from one to another orally, but later, probably about the second century A.D., written documents of medical advice began to be circulated, and culminated in the writings of the Hippocratic and Cnidian schools. The patient passed some days at the healing centres, where the united prayers of the priests and patient were offered up for a cure. The patient was also instructed by the priests in the religion and superstition to help a cure by suggestion. Then the patient was put to sleep in a certain place and the healing god, probably a priest, appeared to him.

The Chadwick Chapter in the History of Medicine.

Sir WILLIAM COLLINS said that Chadwick might well be called the father of English sanitary sciences. He belonged to the noble army of early Victorians, and was born in 1801. His father was a journalist and editor of *The Statesman*, and

Chadwick himself after being called to the Bar wrote largely for the press. During the first great cholera epidemic (1831) he studied its causes. The conditions under which the poor lived and died, and the utter inadequacy of sanitary arrangements at that period, claimed his attention, and in 1832 the Commission was appointed to investigate the Poor Law, and Chadwick was appointed commissioner. He did a great work in ameliorating the conditions, and achieved legislation on the employment of children in factories. It was due to his survey of the overcrowded parts of our towns and cities that the sanitary reform was introduced into Great Britain which eventually led to this country giving the lead to the other nations of the world as regards sanitation. Chadwick's own work and that of his school stood for solid achievement in the advances of hygiene and sanitation, the great hand-maidens of medicine. He lived to see the vindication of his theories, and died in 1890 after a most useful life; his name was remembered the world over as a pioneer in sanitary science, and was undoubtedly worthy of a place in the history of medicine.

Dr. HUNTER gave an account, by a diagrammatic map, of the sanitary reforms made in the time of Chadwick. He pointed out that the death rate is now one-eighth of what it was fifty years ago. He gave statistics of the decrease of typhoid, scarlet fever, diphtheria, measles, and whooping-cough.

Anatomy.

Mr. W. G. SPENCER described an *Epitome* of Vesalius on vellum in the British Museum Library; it was once the property of Richard Meado and about 1754 was sold for £8 12s. The only other known vellum copy was in the library at Louvain for 371 years, but there was proof that it was burnt when the library was destroyed in 1914. Vesalius apparently intended the text for the common man rather than for the use of artists and medical students; he demonstrated the *nudo malo* and female bodies, always taking the most perfect specimens of young adults. Afterwards five muscle diagrams were shown, giving the muscles contracting in motion, and two or three diagrams of skeletons.

Dr. LAIGNEUR-LAVASTINE (Paris) described how throughout the ages symbolism had been applied to anatomy. The astrologer established a relation between the planets and parts of the body. The moon dominated the brain, the sun the heart, Jupiter and Mercury the liver, Saturn the spleen, the skeleton, the joints, cartilages, and right ear, Venus the throat, the veins, the internal generative organs, the scalp and the features, such as chin and cheek. The Cabalists attributed the different organs and functions of man to the twelve simple letters of the Hebrew alphabet. This ancient mediæval symbolism was not altogether to be despised, for it was the foundation on which scientific knowledge grew, the method of conserving it, the frame to incorporate it and transmit to our descendants the scientific inheritance laboriously acquired by observation of nature.

Professor W. WRIGHT spoke on Leonardo da Vinci's work on the structure of the heart. Owing to da Vinci's interest in and great knowledge of mathematics it was only to be expected that he should have given special attention to the circulatory system. The three great anatomists of that period were Leonardo da Vinci, who died in 1519, Eustachius, who died in 1574, and Vesalius, who died in 1554. At that time the difficulties of research were very great owing to the lack of bodies to dissect and the lack of preservatives. Leonardo da Vinci mentions doing his dissections in the dead of night. One can imagine the scene taking place in the old stone buildings of Rome and Florence in the flickering candle light, the mutilated and quartered bodies, and the stench. The coarseness of the surroundings must have been greatly increased by the fact that the period was one of great superstition and appalling crime. Professor Wright concluded by giving a description of some diagrams of Leonardo da Vinci.

Dr. LANDER, in a paper on women as anatomists, said that women students of anatomy might be divided into five groups, according as their objective was midwifery, surgery, philosophy, dilettantism, or professional anatomy. He gave short biographical accounts of the various famous women surgeons known in history, starting with Theodosia, martyred in the reign of Diocletian, following with women at Salerno, and coming down to the eighteenth century, when isolated women still continued to practise surgery in spite of the proceedings against them. In midwifery women had always held a prominent position, though often practising without knowledge and innocent of all anatomy. France

was the first country to educate midwives adequately to their task, Louise Bourgeois in the sixteenth century being perhaps the most famous. Amongst English midwives, Mrs. Jane Sharp, Mrs. Sarah Stone, and Mrs. Clark were advocates of teaching anatomy to midwives. The women philosophers went back to the time of Pythagoras, whose wife carried on his school after his death. From the fifteenth to the eighteenth century many women studied anatomy in the Italian universities; the University of Bologna produced several professional women anatomists, the most famous of whom was Anna Merandi, who married the painter and sculptor John Manzolini; she learnt modelling from her husband and far surpassed him. After his death she became a teacher of anatomy in the University.

Dr. E. T. WRIGHT gave a very interesting account of Galen's knowledge of anatomy, tracing it back through his early work, and Mrs. SINGER read a paper on a thirteenth-century Latin translation of the sixth book of the *Epidemics* in the library of St. John's College, Cambridge. It had a preface in Latin.

In a paper on the beginnings of anatomical teaching in the United States Dr. KRUMBHAR said that anatomy was studied in the States from the early pilgrim times, but, as in other countries, there was a difficulty in acquiring material for dissection, and in 1647 Massachusetts passed a resolution to provide the body of a criminal once in four years. He illustrated his subsequent remarks by portraits of anatomists and pictures of buildings.

Aerostatics.

Dr. F. J. PORTER broke new ground in a paper on "Doctors and the dawn of aërostation." He enlarged on the part played by doctors in the conquest of the air since 1783. Amongst those whose scientific discoveries had aided flight were Joseph Black, Priestley, and Lavoisier. The Frenchman Pilâtre Rozier was the first to use hot air for a balloon, and the Scotsman Titler the first to do so in England. He gave some account of the invention of the Italian Lunardi, and of Jeffries and Blanchard, and concluded by a reference to the controversy between the adherents of flying by hot air and those of flying by gas.

An English Rural Practitioner of the Seventeenth Century.

Dr. N. G. HORNER read a paper entitled "John Westover of Wedmore," based upon an old manuscript journal illustrating rural medical practice in the West of England at the end of the seventeenth century. John Westover belonged to a family which lived at Wedmore in Somersetshire for 300 years. He was born in 1643 and died in 1706, and left behind him in the house where he lived a journal, or day-book, which has been preserved ever since by the subsequent tenants. The book gives a daily record of his medical and surgical practice, and of the business of his farm, during fifteen years—1686 to 1701. Nearly every item contains a note of the fee charged and the amount actually paid. Dr. Horner showed the book and gave a few extracts from it, to indicate the range of Westover's practice and his fees, and also the manner in which he recorded his patients' ailments and the remedies he prescribed. The commonest complaints were "itch" and "wormes." He had no obstetrical practice, but treated a great many fractures and dislocations. In 1680, on the death of his father (who was also a surgeon), he built a stone outhouse for the accommodation of insane patients who came to board with him; many entries in the journal refer to these in-patients and the fees paid by their relatives. Westover's fees were sometimes paid in money, sometimes in work done on his farm, sometimes in goods. The debt was usually paid by instalments, and part of it was often forgiven. His handwriting is difficult to read, and the spelling is eccentric, but the document gives an idea of the work and character of a country general practitioner in England 250 years ago.

History of British Pharmacy.

Mr. J. B. GILMOUR, in an historical sketch of British pharmacy, mentioned that the first apothecary's shop was established in London in the fourteenth century, and in Edinburgh in the fifteenth and sixteenth centuries, though drugs and spices were already being sold by grocers. Later a Royal Charter was granted, protecting apothecaries against this irregular practice. In the seventeenth century, in the time of Boyle, mercury was introduced into medicine, and chemical

ratories were formed. Later, pharmaceutical laws were issued, and systematic inspection of shops to prevent impure drugs being sold was instituted; in the nineteenth century, numerous cases of poisoning by arsenic, a bill was passed restricting the sale of poisonous drugs, and in 1921 a Dangerous Drugs Act came into force to attempt to safeguard the public from opium traffic. The Pharmaceutical Society of Great Britain was formed to raise the status of the professionally trained pharmacists and protect the public, and, on the whole, it has succeeded in doing.

Hiera Picta.

Dr. C. J. S. THOMPSON, M.B.E., in his paper on *hiera picta*, traced the history of this ancient remedy from the time of its mention in the fifth century B.C. The name meant "Holy picture," and according to tradition it was first used in the temples of Asclepius in Greece. Its chief ingredients were opium and colocynth, and formulae were given by Paeonius, Alexander of Tralles, Archigenes, Theodoretus, Galen, Rufus, Aetius, Myrepsus, and others. It became official in the first Pharmacopoeia in 1498. In was included in the London Pharmacopoeia of 1627 and continued in further editions down to 1851. Mr. Thompson said that there was still a demand for it in Great Britain, Belgium, France, and other parts of Europe, and it was sold in the pharmacies of these countries; it was in Damascus, Rome, and Alexandria before the Christian era. It had thus survived over two thousand years.

The Pomander Stick.

Dr. MICHAEL FOSTER, in a paper on the pomander stick, described the sticks carried by doctors during the seventeenth and eighteenth centuries. The heads of these canes were of pear or apple shape and contained a receptacle for aromatic substances, which were regarded as a sovereign protection against plague and other diseases. He mentioned various uses of pomander sticks, those with a top which could be screwed, in which aromatic substances could be placed, and others with a perforated head like a vinaigrette, containing sponge soaked in aromatic vinegar. He thought these canes were exceedingly rare, and only knew about twelve actually existing. He mentioned that the canes carried by the apothecaries of that time differed greatly from the pomander stick, and that the surgeons and apothecaries also carried a different one, the pomander stick being characteristic of the physician.

Visit to Barbers' Hall.

In the afternoon of Wednesday, July 19th, members of the Congress visited Barbers' Hall, in Monkwell Street, and were received by the Master, who welcomed them to this interesting memorial of the ancient guild life of the City of London. He then called on Mr. Weston, a past master of the company, who described the Hall, its history, and its treasures. Mr. Weston's learned address was listened to with great interest by a large company, seated under Holbein's famous picture of Henry VIII granting his Charter to the United Companies of Barbers and Surgeons. He described the Hall as the cradle of surgery in England, and briefly spoke of the origins of barbers and surgeons and their early craft guilds. The Hall the Company had been on this site under continuous membership since the end of the fourteenth century. He showed the first Charter granted to the Barbers of the ward IV, and the fifteenth-century Black Book of finances of the joint Company, containing a copy of the earliest licence to practise surgery in England. He next showed subsequent charters and other valuable possessions of the Company, including the silver-gilt cup given them by Henry VIII as a new year's present; Charles II's gift of a silver cup in the shape of a crowned Bosobel oak; and the silver punch-bowl presented by Queen Anne, and described *Punch* as big enough to bath the baby in. Mr. Weston then told the story of Holbein's masterpiece—the most famous and most valuable picture in the City of London; how it was returned safely to the Hall after being borrowed by Charles I; how it was removed for safety to Moorfields during the Great Fire of London; how it was kept in the National Gallery strong-room during the air raids; and lastly, how it escaped purchase by an American millionaire. He pointed out Thomas Vicary and the other surgeons and barbers, the royal physicians and the King's apothecary, sitting humbly on either side of their contemptuous monarch, and explained that the colours of the picture could be restored in the usual way because it was painted upon a surface of gold-leaf laid on smooth oak panels.

St. Bartholomew's Hospital.

On Friday afternoon the members of the Congress visited St. Bartholomew's Hospital, when an historical address on the hospital was given by Sir D'Arcy Power.

Entertainments.

On Tuesday the Lord Mayor and Lady Mayoress held a reception at the Mansion House, and the Lord Mayor welcomed the members to the City of London in a few well-chosen words. In the evening a reception was given by Sir James Purves Stewart and Lady Purves Stewart. A musical conversation was held at the Wellcome Historical Medical Museum on Wednesday evening. The visitors numbered about two hundred, and were received by Mr. H. S. Wellcome, Mr. C. J. S. Thompson, and Dr. Andrew Balfour. On Thursday evening the members of the Congress were entertained at a reception by the Vice-Chancellor of the University of London and Mrs. H. J. Waring. There was a large attendance at the banquet which was held at the Hotel Cecil on Friday evening. Dr. Singer presided, and was supported by Sir Humphry Rolleston, Sir Frederick Kenyon, Sir D'Arcy Power, and the Master of the Apothecaries' Company. The toast of "The International Society of the History of Medicine" was responded to by Dr. Tricot-Royer, and Sir Frederick Kenyon replied on behalf of the guests. On Saturday the members of the Congress joined in an excursion to Windsor Castle and up the river Thames.

(To be continued.)

CONFERENCE ON MENTAL DEFICIENCY.

A two days' Conference on Mental Deficiency, held under the auspices of the Central Association for Mental Welfare, was opened at the Caxton Hall, Westminster, on Wednesday, July 26th. Sir LESLIE SCOTT, K.C., the Solicitor-General, presided.

Crime and Mental Deficiency.

Sir BRYAN DONKIN argued for attaching a more comprehensive meaning to the term "mental deficiency" than its present technical and artificial one. It should include every kind of insanity. Such co-ordinate arrangement of the various groups of mentally disordered or defective persons under one comprehensive heading might lead to a better understanding between thoughtful jurists and physicians on the matter of criminal responsibility. It seemed to him that the only proof of defective mind (in whatever category such may be classed) that a court of justice should require when a plea of responsibility was set up ought to be based on the same kind of evidence as is now required in cases of certifiable insanity. He was strongly opposed to any suggestion likely to lead to decision on a prisoner's responsibility to the law being left to medical evidence alone.

Dr. NORWOOD EAST said that his experience as a prison medical officer had led him to the opinion that the criminal defective might be considered from two points of view, according to whether the defect had been recognized before or after conviction and sentence. Those who escaped detection before conviction could be observed whilst serving their sentence, and transferred if necessary to an institution for defectives under Section 9 of the Mental Deficiency Act. Owing to the disadvantage of a conviction being recorded against such a person prison medical officers endeavoured to diagnose the defect before trial, and in this they were assisted by the frequency of magisterial remands for inquiry. A medical examination alone did not suffice. Information must be got of the individual's early history, especially of the years between leaving school and arrest. The manner of crime might assist in deciding whether insanity or defect was responsible for the offence. The vocabulary test was one of the most valuable single tests, but the most important was the prisoner's capacity to earn his own living and to conform to social requirements. The greatest difficulty arose in dealing with adolescents whose conduct suggested defect, but the experienced clinician remembered that some cases of this nature settled down normally after adolescence and proved a hasty early diagnosis of defectiveness to have been erroneous. The tendency to extend the description of certain types of defectives beyond the strict statutory definition might lead to complacency in diagnosis, to a false idea of knowledge, and a failure to study adequately the borderland group. In conclusion, Dr. East spoke of the desirability of establishing treatment clinics for cases of mental disorder and defect. Observation and treatment at a clinic would prevent many cases from committing a criminal action.

The CHAIRMAN said that the question of responsibility for crime in a case where there was mental defect was essentially one of degree. Whether enough consideration had been given to the acts of physical impulsions in crime he did not know; but there was paramount need for greater study of the subject. The Conference, however, was concerned not so much with legal punishment as with the treatment of the defective so as to prevent his commission of acts which in a normal person would be called crime. People must be made to realize that mental illness (of whatever sort) was not a disgrace. It was necessary to educate the public, and he would like to see this educational campaign launched. The problem was a health problem, and in his opinion the Board of Control should be under the Ministry of Health.

Mr. A. H. FREVOR (Legal Commissioner, Board of Control) then took the chair.

Dr. T. B. HYSLOP recognized the term "mental deficiency" as one of convenience derived from usage. Illustrating his remarks by reference to the teaching of that great pioneer, the late Dr. Hughlings Jackson, Dr. Hyslop said that in insanity as in mental deficiency we were apt to concentrate our attention on the abnormalities of action of the "undamaged remainder," and neglect the actual disease which resulted in disorder of the controlling mechanism itself. Now that the nation had reached the "stadium convalescens" after the war, efforts on behalf of those who, through no fault of their own, were deprived of the ability to maintain themselves should be increased.

Mr. HAROLD COX thought that steps should be taken to prevent mental defectives from being brought into the world. He advocated sterilization of mental defectives, but was opposed to compulsory sterilization.

The CHAIRMAN said the whole subject had been referred to the Medical Committee of the Association.

Dr. W. A. PORTS (Medical Adviser to the Birmingham Justices) agreed with Dr. East that not more than 5 per cent. of prisoners were defective. The remaining percentage should be studied. The solution of the problem regarding other prisoners would be got by a study of mental defect. Amongst others who took part in the discussion were Dr. RICKETT (Newcastle) and Dr. SHAKELTON (Bradford).

Mental Defectives in the Courts.

In the afternoon session, when Dr. W. A. PORTS presided, a paper on the need for correlation between the courts, the prison departments, and the Mental Deficiency Act Committees was read by Mr. STUART DEACON, stipendiary magistrate, Liverpool, who, speaking from over twelve years' experience in Liverpool, declared his belief that the Mental Deficiency Act was a great boon, more particularly to the poorer members of the community. Many heart-breaking problems had been solved for magistrates by its provisions. He believed that the spirit of the police-court administration should be rather the cure of a patient than the punishment of an offender. In the wise administration of the Act in our police courts, more particularly with regard to children and young adults, there lay not only a certain reduction of the ranks of potential criminals, but the opening of an avenue of research into the causes of crime, the penetration of which by the joint and experienced minds of magistrates, prison officials, and mental experts acting in whole-hearted co-operation might lead to the diminution of the criminal population by numbers at present inconceivable.

Mrs. PATRICK R. GREEN dealt with the difficult position of justices in regard to hearing petitions presented by the local authorities or by the guardians of the defectives. Justices generally acted on the principle that "prevention is better than cure"; if defectives were not safeguarded early enough they generally came before the courts sooner or later. Legislation was urgently needed by which it would be made obligatory to deal with the defective delinquent under the Mental Deficiency Act; in addition there should be a statutory obligation on all courts to provide the services of a medical expert to advise justices on the mental condition of persons charged. The visitors of the local voluntary associations had done magnificent work. Through their efforts the working of the Act had been made possible.

The CHAIRMAN differentiated the mental defectives and the psychopathic cases. The latter got no benefit from being in an institution for mental defectives, and their presence often led to unfortunate occurrences.

Dr. HUGHES (Stoke-on-Trent) thought that intelligence defect and moral defect were not so highly correlated as had been supposed. He referred to the various methods he had

adopted to get hold of the delinquent as early as possible. He had got his best results in the cases brought by the parents themselves. In his opinion moral imbeciles should be sent to industrial schools. The moral effect of a conviction being recorded against anyone was enormous. To prevent this cases must be got early.

Dr. THOMSON (Birmingham) criticized Sir Leslie Scott's statement that mental deficiency was to be regarded as other diseases, and that the public should be taught that no stigma attached to it. This was a dangerous doctrine, for it was the stigma which prevented the amount of mental deficiency being greater than it was.

Dr. HUNTER BOND (Board of Control) urged the need of co-ordination between medical staffs of institutions and those occupying public positions. There should be correlation between the prison medical officers and the medical officers of mental hospitals. He reiterated his plea for fluidity of service. Regarding our present procedure, only the prima facie cases were sent for medical examination. The goal to be aimed at was that every prisoner when he came before the court and was found to have committed an offence should have his case medically inquired into. The discussion was continued by Dr. C. W. LITTLE (Newcastle), Dr. BREWER (Swindon), and others.

Address by the President of the Board of Education.

On the second day of the Conference the chair was taken at the morning session by Lieut.-Colonel W. E. RALEY, President of the Association Education Committees. The opening address was delivered by the Right Hon. H. A. L. FISHER, President of the Board of Education.

Mr. FISHER said that there was little difference of opinion with regard to the general principles which formed the public policy of the State. The first principle was that every child capable of profiting by a course of education in a public elementary school should go to one. The second, that every child unable, by reason of mental deficiency, to profit by that education should be removed; for not only did such a child derive no benefit itself, but its presence acted as a drag and an incubus upon the education of its schoolmates. The third principle was that the children who were so excluded should be divided into two classes—those who could be educated to earn the whole or a part of their livelihood, and could be taught to manage their own affairs and to take part in society as decent citizens, and those who failed to satisfy these tests. The first class, it had been decreed, should be educated in special schools under the Board of Education, while the second class should be handed over to the Board of Control, for supervision at home or custodial care. The Board was educating at present in special schools for the mentally defective 15,138 children, but it was calculated that the total number of such children in England and Wales was 31,000. The total cost of educating the children in special schools was £436,000; if an attempt were made to educate the whole body of 31,000 children who could be classed as mentally defective, day school provision of 19,000 and residential school provision of 12,000 would be required, and an additional expenditure entailed of £977,000, upon which the Board's grant would be approximately £480,000. The Board was not considering the abolition of the special teaching of feeble-minded children under proper conditions altogether, nor was it exploring the lowering of the school-leaving age in special schools from 16 to 14. It was, however, considering the reduction of the teaching cost in its special schools, and unless it could effect some reduction in the teaching cost, and obtain the assistance of the teachers' organizations in effecting this, it was vain to hope that they should be in a position, within a measurable time, of covering any considerable part of the fresh ground which they ought to occupy with as little delay as possible.

Occupation Centres.

Dr. H. B. BRACKENBURY (who was unable to be present) contributed a paper on economic difficulties which prohibit the development of special schools. He expressed a fear lest the Board of Education, in looking for a way to reduce its expenditure, might reduce the money spent on the care and education of mentally defective children. Admittedly, such care and education were costly, and it was only fair to ask for proposals by which a reduction in cost might be effected. After considering certain suggestions put forward to this end, Dr. Brackenbury urged that a plan deserving special attention was that of the attendance of low-grade feeble-minded

children at occupation centres for training and teaching. The advocacy of occupation centres involved no sinister intention of supplanting special schools. They would not replace or act as alternatives to special schools for high-grade children. Some such suggestion deserved consideration to prevent many thousands of feeble-minded children being neglected or abandoned.

The discussion which followed was opened by Mr. SPURLEY HRY (Director of Education, Manchester). Amongst those who took part were Dr. THOMSON (Birmingham) and Dr. DOUGLAS-TURNER. In the opinion of the latter the only way in which the present difficulties could be met was by extending the system of occupation centres.

In the afternoon the chair was taken by Sir COURTAULD THOMSON (Chairman of the National Council for Mental Hygiene). Mrs. ANDERSON (Case Secretary, C.A.M.W.) said that there were a great number of children between the ages of 7 and 16 who had been tried at a special school and "excluded," or in areas where there were no special schools had been turned out of elementary schools because they could not be taught there. If these children were left to themselves the inevitable result was deterioration in mental and moral condition. Occupation centres had been tried to meet this need. Low-grade defectives could be taught to do housework very well, and were happy in doing it. The occupation centre was an enormous boon to the overworked and nerve-wrecked mother. Mrs. Anderson related her experiences of occupation centres and considered it possible to run such a centre successfully at the rate of £7 a head. In her opinion defective children had a great deal of character and were very conscious of a right or wrong atmosphere. The earnest and devoted worker had a recompense in watching this unfolding and in the love and affection which these unfortunate little ones were so eager to give her.

Miss RUTH DARWIN (Commissioner, Board of Control) read a paper on working hostels and other institutional methods of dealing with defectives. She believed, that besides institutional treatment other methods should now be tried.
